# Stock Assessment and Fishery Evaluation Report for the King and Tanner Crab Fisheries of the Bering Sea and Aleutian Islands Regions 

## Table of Contents

Summary
Introduction ..... I-1
Stock Status Definitions ..... I-3
Status Determination Criteria ..... I-4
Crab Plan Team Recommendations ..... I-10
Stock Status Summaries ..... I-12
Stock Assessment Section

1. EBS snow crab ..... 1-1
2. Bristol Bay red king crab ..... 2-1
3. EBS Tanner crab ..... 3-1
4. Pribilof Islands red king crab ..... 4-1
5. Pribilof Islands blue king crab ..... 5-1
6. Saint Matthew blue king crab ..... 6-1
7. Norton Sound red king crab ..... 7-1
8. Aleutian Islands golden king crab assessment ..... 8-1
9. Pribilof Islands golden king crab ..... 9-1
10. Western Aleutian Islands red king crab ..... 10-1
Appendix: Crab Economic Summary

## Introduction

The annual stock assessment and fishery evaluation (SAFE) report is a requirement of the North Pacific Fishery Management Council's Fishery Management Plan for Bering Sea/Aleutian Islands King and Tanner Crabs (FMP), and a federal requirement [50 CFR Section 602.12(e)]. The SAFE report summarizes the current biological and economic status of fisheries, total allowable catch (TAC) or Guideline Harvest Level (GHL), and analytical information used for management decisions. Additional information on Bering Sea/Aleutian Islands (BSAI) king and Tanner crab is available on the National Marine Fisheries Service (NMFS) web page at http://www.fakr.noaa.gov and the Alaska Department of Fish and Game (ADF\&G) Westward Region Shellfish web page at: http://www.cf.adfg.state.ak.us/region4/shellfsh/shelhom4.php.

Paralithodes camtschaticus, stocks (Bristol Bay, Pribilof Islands, Norton Sound and Adak), 2 blue king crab, Paralithodes platypus, stocks (Pribilof Islands and St Matthew Island), 2 golden (or brown) king crab, Lithodes aequispinus, stocks (Aleutian Islands and Pribilof Islands), southern Tanner crab Chionoecetes bairdi hereafter referred to as Tanner crab, and snow crab Chionoecetes opilio. All other crab stocks in the BSAI are exclusively managed by the State of Alaska (SOA).

The Crab Plan Team (CPT) annually assembles the SAFE report with contributions from ADF\&G and the NMFS. This SAFE report is presented to the North Pacific Fishery Management Council (NPFMC) and is available to the public on the NPFMC web page at:
http://fakr.noaa.gov/npfmc/membership/plan teams/CRAB team.htm. Due to a process to accommodate specific fishery and data availability needs to determine overfishing level (OFL) determinations, and annual catch limit (ACL) requirements, the CPT reviews assessments in a staggered time frame. Additionally, based upon consideration of stock prioritization including assessment methods and data availability, some stocks are assessed on an annual basis while others are assessed less frequently. The CPT reviews one assessment in January (Norton Sound red king crab), two assessments in May on a three-year cycle (WAI red king crab and Pribilof Islands golden king crab) and the remaining assessments (Bristol Bay red king crab, EBS snow crab, EBS Tanner crab, Saint Matthew blue king crab, Pribilof Island red king crab and Pribilof Island blue king crab, Aleutian Islands golden king crab,) in September (Table 1). Pribilof red king crab is assessed biennially while Pribilof blue king crab is assessed on a threeyear cycle. Stocks can be assessed more frequently on a case-by-case basis should data indicate that it is necessary.

Table 1 Ten BSAI crab stocks: Schedule for review by the CPT and SSC and Assessment frequency

| Stock | CPT review and recommendations to SSC | SSC review and recommendations to Council | Assessment frequency | Year of next Assessment |
| :---: | :---: | :---: | :---: | :---: |
| Norton Sound red king crab <br> (NSRKC) | January | February | Annual | 2019 |
| Aleutian Is. golden king crab <br> (AIGKC) | May | June | Annual | 2019 |
| Pribilof Is. blue king crab <br> (PIBKC) | May | June | Biennial | 2019 |
| Pribilof Is. golden king crab <br> (PIGKC) | May | June | Triennial | 2020 |
| Western Aleutian Is. red king crab (WAIRKC) | May | June | Triennial | 2020 |
| EBS snow crab | September | October | Annual | 2019 |
| Bristol Bay red king crab <br> (BBRKC) | September | October | Annual | 2019 |
| EBS Tanner crab | September | October | Annual | 2019 |
| Pribilof Is. red king crab (PIRKC) | September | October | Biennial | 2019 |
| Saint Matthew blue king crab <br> (SMBKC) | September | October | Annual | 2019 |

Based upon the assessment frequency described in Table 1, the CPT provides recommendations on OFL, acceptable biological catch (ABC) and stock status specifications for review by the NPFMC Science and Statistical Committee (SSC) in February (NSRKC) and June (WAIRKC, PIGKC, PIBKC, AIGKC) and October (BBRKC, EBS Snow crab, EBS Tanner crab, SMBKC, PIRKC). The rationale for this staggered review process is the following: The stocks with summer fisheries as well as those established on catch data only have specifications set in June. The stocks which employ data from the EBS NMFS trawl survey thus cannot be assessed until survey data are available in early September. Summer catch data for NSRKC however are not available in time for fall specifications, nor is assessing this stock with the June timing feasible as the CDQ fishery can open as early as May thus this stock is assessed in the winter. Additional information on the OFL and ABC determination process is contained in this report.

The CPT met from September 10-13, 2018 in Seattle, WA to review the final stock assessments as well as additional related issues, in order to provide the recommendations and status determinations contained in this SAFE report. This final 2018 Crab SAFE report contains all recommendations for all 10 stocks including those whose OFL and ABC were previously determined in February and June 2018. This SAFE report will be presented to the NPFMC in October for their annual review of the status of BSAI Crab stocks.

Members of the team who participated in this review include the following:
Bob Foy (Chair), Ben Daly (Vice-Chair), Katie Palof, Miranda Westphal, Brian Garber-Yonts, Ginny Eckert, Krista Milani, André Punt, Buck Stockhausen, Cody Szuwalski, Martin Dorn, Shareef Siddeek, Bill Bechtol and Diana Stram.

## Stock Status Definitions

The FMP (incorporating all changes made following adoption of Amendment 24) contains the following stock status definitions:

Acceptable biological catch (ABC) is a level of annual catch of a stock that accounts for the scientific uncertainty in the estimate of OFL and any other specified scientific uncertainty and is set to prevent, with a greater than 50 percent probability, the OFL from being exceeded. The ABC is set below the OFL.

ABC Control Rule is the specified approach in the five-tier system for setting the maximum permissible ABC for each stock as a function of the scientific uncertainty in the estimate of OFL and any other specified scientific uncertainty.

Annual catch limit (ACL) is the level of annual catch of a stock that serves as the basis for invoking accountability measures. For EBS crab stocks, the ACL will be set at the ABC.

Total allowable catch (TAC) is the annual catch target for the directed fishery for a stock, set to prevent exceeding the ACL for that stock and in accordance with section 8.2.2 of the FMP.

Guideline harvest level (GHL) means the preseason estimated level of allowable fish harvest which will not jeopardize the sustained yield of the fish stocks. A GHL may be expressed as a range of allowable harvests for a species or species group of crab for each registration area, district, subdistrict, or section.

Maximum sustainable yield (MSY) is the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions. MSY is estimated from the best information available.

FMSY control rule means a harvest strategy which, if implemented, would be expected to result in a longterm average catch approximating MSY.
$\underline{B}_{\text {MSY }}$ stock size is the biomass that results from fishing at constant $\mathrm{F}_{\text {MSY }}$ and is the minimum standard for a rebuilding target when a rebuilding plan is required.

Maximum fishing mortality threshold (MFMT) is defined by the FofL control rule and is expressed as the fishing mortality rate.

Minimum stock size threshold (MSST) is one half the $\mathrm{B}_{\text {MSY }}$ stock size.
Overfished is determined by comparing annual biomass estimates to the established MSST. For stocks where MSST (or proxies) are defined, if the biomass drops below the MSST (or proxy thereof) then the stock is considered to be overfished. For crab stocks, biomass for determining overfished status is estimated on February 15 of the current year and compared to the MSST established by the NPFMC in October of the previous year.

Overfishing is defined as any amount of catch in excess of the overfishing level (OFL). The OFL is calculated by applying abundance estimates to the $\mathrm{F}_{\text {OFL }}$ control rule which is annually estimated according the tier system (see Chapter 6.0 in the FMP).

## Status Determination Criteria

The FMP defines the following status determination criteria and the process by which these are defined following adoption of amendment 24 and 38.

Status determination criteria for crab stocks are calculated using a five-tier system that accommodates varying levels of uncertainty of information. The five-tier system incorporates new scientific information and provides a mechanism to continually improve the status determination criteria as new information becomes available. Under the five-tier system, overfishing and overfished criteria and ABC levels for most stocks are annually formulated. The ACL for each stock equals the ABC for that stock. Each crab stock is annually assessed to determine its status and whether (1) overfishing is occurring or the rate or level of fishing mortality for the stock is approaching overfishing, (2) the stock is overfished or the stock is approaching an overfished condition, and (3) the catch has exceeded the ACL.

For crab stocks, the OFL equals the maximum sustainable yield (MSY) and is derived through the annual assessment process, under the framework of the tier system. Overfishing is determined by comparing the OFL with the catch estimates for that crab fishing year. For the previous crab fishing year, NMFS will determine whether overfishing occurred by comparing the previous year's OFL with the catch from the previous crab fishing year. For the previous crab fishing year, NMFS will also determine whether the ACL was exceeded by comparing the ACL with the catch estimates for that crab fishing year. Catch includes all fishery removals, including retained catch and discard losses, for those stocks where nontarget fishery removal data are available. Discard losses are determined by multiplying the appropriate handling mortality rate by observer estimates of bycatch discards. For stocks where only retained catch information is available, the OFL and ACL will be set for and compared to the retained catch.

The NMFS will determine whether a stock is in an overfished condition by comparing annual biomass estimates to the established MSST. For stocks where MSST (or proxies) are defined, if the biomass drops below the MSST (or proxy thereof) then the stock is considered to be overfished. MSSTs or proxies are set for stocks in Tiers 1-4. For Tier 5 stocks, it is not possible to set an MSST because there are no reliable estimates of biomass.

If overfishing occurred or the stock is overfished, section 304(e)(3)(A) of the Magnuson-Stevens Act, as amended, requires the NPFMC to immediately end overfishing and rebuild affected stocks.

The Magnuson-Stevens Act requires that FMPs include accountability measures to prevent ACLs from being exceeded and to correct overages of the ACL if they do occur. Accountability measures to prevent TACs and GHLs from being exceeded have been used under this FMP for the management of the BSAI crab fisheries and will continue to be used to prevent ACLs from being exceeded. These include: individual fishing quotas and the measures to ensure that individual fishing quotas are not exceeded, measures to minimize crab bycatch in directed crab fisheries, and monitoring and catch accounting measures. Accountability measures in the harvest specification process include downward adjustments to the ACL and TAC in the fishing year after an ACL has been exceeded.

Annually, the NPFMC, SSC, and CPT will review (1) the stock assessment documents, (2) the OFLs and ABCs, and TACs or GHLs, (3) NMFS's determination of whether overfishing occurred in the previous crab fishing year, (4) NMFS's determination of whether any stocks are overfished and (5) NMFS's determination of whether catch exceeded the ACL in the previous crab fishing year.

Optimum yield is defined in Chapter 4 of the FMP. Information pertaining to economic, social and ecological factors relevant to the determination of optimum yield is provided in several sections of the

FMP, including sections 7.2 (Management Objectives), Chapter 11, Appendix D (Biological and Environmental Characteristics of the Resource), and Appendix H (Community Profiles).

For each crab fishery, the optimum yield range is 0 to < OFL catch. For crab stocks, the OFL is the annualized MSY and is derived through the annual assessment process, under the framework of the tier system. Recognizing the relatively volatile reproductive potential of crab stocks, the cooperative management structure of the FMP, and the past practice of restricting or even prohibiting directed harvests of some stocks out of ecological considerations, this optimum yield range is intended to facilitate the achievement of the biological objectives and economic and social objectives of the FMP (see sections 7.2.1 and 7.2.2) under a variety of future biological and ecological conditions. It enables the SOA to determine the appropriate TAC levels below the OFL to prevent overfishing or address other biological concerns that may affect the reproductive potential of a stock but that are not reflected in the OFL itself. Under FMP section 8.2.2, the SOA establishes TACs at levels that maximize harvests, and associated economic and social benefits, when biological and ecological conditions warrant doing so.

## Five-Tier System

The OFL and ABC for each stock are estimated for the upcoming crab fishing year using the five-tier system, detailed in Table 2 and Table 3. First, a stock is assigned to one of the five tiers based on the availability of information for that stock and model parameter choices are made. Tier assignments and model parameter choices are recommended through the CPT process to the SSC. The SSC recommends tier assignments, stock assessment and model structure, and parameter choices, including whether information is "reliable," for the assessment authors to use for calculating the proposed OFLs and ABCs based on the five-tier system.

For Tiers 1 through 4, once a stock is assigned to a tier, the determination of stock status level is based on recent survey data and assessment models, as available. The stock status level determines the equation used in calculating the Fofl. Three levels of stock status are specified and denoted by "a," "b," and "c" (see Table 2). The $\mathrm{F}_{\text {MSY }}$ control rule reduces the $\mathrm{F}_{\mathrm{OFL}}$ as biomass declines by stock status level. At stock status level "a," current stock biomass exceeds the BMSY. For stocks in status level "b," current biomass is less than $B_{\text {MSY }}$ but greater than a level specified as the "critical biomass threshold" $(\beta)$.

In stock status level "c," the ratio of current biomass to $\mathrm{B}_{\text {MSY }}$ (or a proxy for $\mathrm{B}_{\text {MSY }}$ ) is below $\beta$. At stock status level "c," directed fishing is prohibited and an FofL at or below FMSY would be determined for all other sources of fishing mortality in the development of the rebuilding plan. The Council will develop a rebuilding plan once a stock level falls below the MSST.

For Tiers 1 through 3, the coefficient $\alpha$ is set at a default value of 0.1 , and $\beta$ set at a default value of 0.25 , with the understanding that the SSC may recommend different values for a specific stock or stock complex as merited by the best available scientific information.

In Tier 4, a default value of natural mortality rate (M) or an M proxy, and a scalar, $\gamma$, are used in the calculation of the $\mathrm{F}_{\mathrm{OFL}}$.

In Tier 5, the OFL is specified in terms of an average catch value over an historical time period, unless the SSC recommends an alternative value based on the best available scientific information.

Second, the assessment author prepares the stock assessment and calculates the proposed OFLs by applying the $\mathrm{F}_{\text {ofl }}$ and using the most recent abundance estimates. The assessment authors calculate the proposed ABCs by applying the ABC control rule to the proposed OFL.

Stock assessment documents shall:

- use risk-neutral assumptions;
- specify how the probability distribution of the OFL used in the ABC control rule is calculated for each stock; and
- specify the factors influencing scientific uncertainty that are accounted for in calculation of the probability distribution of the OFL.

Second, the CPT annually reviews stock assessment documents, the most recent abundance estimates, the proposed OFLs and ABCs, and complies the SAFE. The CPT then makes recommendations to the SSC on the OFLs, ABCs, and any other issues related to the crab stocks.

Third, the SSC annually reviews the SAFE report, including the stock assessment documents, recommendations from the CPT, and the methods to address scientific uncertainty.

In reviewing the SAFE, the CPT and the SSC shall evaluate and make recommendations, as necessary, on:

- the assumptions made for stock assessment models and estimation of OFLs;
- the specifications of the probability distribution of the OFL;
- the methods to appropriately quantify uncertainty in the ABC control rule; and
- the factors influencing scientific uncertainty that the SOA has accounted for and will account for on an annual basis in TAC setting.

The SSC will then set the final OFLs and ABCs for the upcoming crab fishing year. The SSC may set an ABC lower than the result of the ABC control rule, but it must provide an explanation for setting the ABC less than the maximum ABC .

As an accountability measure, the total catch estimate used in the stock assessment will include any amount of harvest that may have exceeded the ACL in the previous fishing season. For stocks managed under Tiers 1 through 4, this would result in a lower maximum ABC in the subsequent year, all else being equal, because maximum ABC varies directly with biomass. For Tier 5 stocks, the information used to establish the ABC is insufficient to reliably estimate abundance or discern the existence or extent of biological consequences caused by an overage in the preceding year. Consequently, the subsequent year's maximum ABC will not automatically decrease. However, when the ACL for a Tier 5 stock has been exceeded, the SSC may decrease the ABC for the subsequent fishing season as an accountability measure.

## Tiers 1 through 3

For Tiers 1 through 3, reliable estimates of $\mathrm{B}, \mathrm{B}_{\mathrm{MSY}}$, and $\mathrm{F}_{\mathrm{MSY}}$, or their respective proxy values, are available. Tiers 1 and 2 are for stocks with a reliable estimate of the spawner/recruit relationship, thereby enabling the estimation of the limit reference points $B_{\text {MSY }}$ and $\mathrm{F}_{\text {mSY. }}$

- Tier 1 is for stocks with assessment models in which the probability density function (pdf) of $\mathrm{F}_{\text {MSY }}$ is estimated.
- Tier 2 is for stocks with assessment models in which a reliable point estimate, but not the pdf, of $\mathrm{F}_{\text {MSY }}$ is made.
- Tier 3 is for stocks where reliable estimates of the spawner/recruit relationship are not available, but proxies for $\mathrm{F}_{\text {MSY }}$ and $\mathrm{B}_{\text {MSY }}$ can be estimated.

For Tier 3 stocks, maturity and other essential life-history information are available to estimate proxy limit reference points. For Tier 3, a designation of the form " $F_{x}$ " refers to the fishing mortality rate associated with an equilibrium level of fertilized egg production (or its proxy such as mature male biomass at mating) per recruit equal to $\mathrm{X} \%$ of the equilibrium level in the absence of any fishing.

The OFL and ABC calculation accounts for all losses to the stock not attributable to natural mortality. The OFL and ACL are total catch limits comprised of three catch components: (1) non-directed fishery discard losses; (2) directed fishery discard losses; and (3) directed fishery retained catch. To determine the discard losses, the handling mortality rate is multiplied by bycatch discards in each fishery. Overfishing would occur if, in any year, the sum of all three catch components exceeds the OFL.

## Tier 4

Tier 4 is for stocks where essential life-history, recruitment information, and understanding are insufficient to achieve Tier 3. Therefore, it is not possible to estimate the spawner-recruit relationship. However, there is sufficient information for simulation modeling that captures the essential population dynamics of the stock as well as the performance of the fisheries. The simulation modeling approach employed in the derivation of the annual OFLs captures the historical performance of the fisheries as seen in observer data from the early 1990s to present and thus borrows information from other stocks as necessary to estimate biological parameters such as $\gamma$.

In Tier 4, a default value of natural mortality rate (M) or an M proxy, and a scalar, $\gamma$, are used in the calculation of the $\mathrm{F}_{\mathrm{OFL}}$. Explicit to Tier 4 are reliable estimates of current survey biomass and the instantaneous M. The proxy $\mathrm{B}_{\text {MSY }}$ is the average biomass over a specified time period, with the understanding that the Council's Scientific and Statistical Committee may recommend a different value for a specific stock or stock complex as merited by the best available scientific information. A scalar, $\gamma$, is multiplied by $M$ to estimate the Fofl for stocks at status levels "a" and "b," and $\gamma$ is allowed to be less than or greater than unity. Use of the scalar $\gamma$ is intended to allow adjustments in the overfishing definitions to account for differences in biomass measures. A default value of $\gamma$ is set at 1.0 , with the understanding that the Council's Scientific and Statistical Committee may recommend a different value for a specific stock or stock complex as merited by the best available scientific information.

If the information necessary to determine total catch OFLs and ACLs is available for a Tier 4 stock, then the OFL and ACL will be total catch limits comprised of three catch components: (1) non-directed fishery discard losses; (2) directed fishery discard losses; and (3) directed fishery retained catch. If the information necessary to determine total catch OFLs and ACLs is not available for a Tier 4 stock, then the OFL and ACL are determined for retained catch. In the future, as information improves, data would be available for some stocks to allow the formulation and use of selectivity curves for the discard fisheries (directed and non-directed losses) as well as the directed fishery (retained catch) in the models. The resulting OFL and ACL from this approach, therefore, would be the total catch OFL and ACL.

## Tier 5

Tier 5 stocks have no reliable estimates of biomass and only historical catch data are available. For Tier 5 stocks, the OFL is set equal to the average catch from a time period determined to be representative of the production potential of the stock, unless the Scientific and Statistical Committee recommends an alternative value based on the best available scientific information. The ABC control rule sets the maximum ABC at less than or equal to 90 percent of the OFL and the ACL equals the ABC .

For Tier 5 stocks where only retained catch information is available, the OFL and ACL will be set for the retained catch portion only, with the corresponding limits applying to the retained catch only. For Tier 5
stocks where information on bycatch mortality is available, the OFL and ACL calculations could include discard losses, at which point the OFL and ACL would be applied to the retained catch plus the discard losses from directed and non-directed fisheries.

Figure 1 Overfishing control rule for Tiers 1 through 4. Directed fishing mortality is 0 below $\beta$.

Table 2 Five-Tier System for setting overfishing limits (OFLs) and Acceptable Biological Catches (ABCs) for crab stocks. The tiers are listed in descending order of information availability. Table 2 contains a guide for understanding the five-tier system.

| Information available | Tier | Stock status level | Fofl | ABC control rule |
| :---: | :---: | :---: | :---: | :---: |
| $B, B_{M S Y}, F_{M S Y}$, and pdf of $F_{M S Y}$ |  | a. $\frac{B}{B_{m s y}}>1$ | $\begin{gathered} F_{O F L}=\mu_{A}=\text { arithmetic mean } \\ \text { of the pdf } \end{gathered}$ |  |

Table 3 A guide for understanding the five-tier system.

- $\quad \mathrm{F}_{\text {OfL }}$ - the instantaneous fishing mortality ( F ) from the directed fishery that is used in the calculation of the overfishing limit (OFL). F $\mathrm{F}_{\mathrm{OL}}$ is determined as a function of:
- $\mathrm{F}_{\text {MSY }}$ - the instantaneous F that will produce MSY at the MSY-producing biomass
- A proxy of $\mathrm{F}_{\text {MSY }}$ may be used; e.g., $\mathrm{F}_{\mathrm{x} \%}$, the instantaneous F that results in $\mathrm{x} \%$ of the equilibrium spawning per recruit relative to the unfished value
- B - a measure of the productive capacity of the stock, such as spawning biomass or fertilized egg production.
- A proxy of B may be used; e.g., mature male biomass
- $\mathrm{B}_{\mathrm{MSY}}$ - the value of B at the MSY-producing level
- A proxy of $B_{\text {MSY }}$ may be used; e.g., mature male biomass at the MSYproducing level
- $\quad \beta$ - a parameter with restriction that $0 \leq \beta<1$.
- $\alpha$ - a parameter with restriction that $0 \leq \alpha \leq \beta$.
- The maximum value of $\mathrm{F}_{\text {ofL }}$ is $\mathrm{F}_{\text {MSY. }}$. $\mathrm{F}_{\text {OFL }}=\mathrm{F}_{\text {MSY }}$ when $\mathrm{B}>\mathrm{B}_{\mathrm{MSY}}$.
- Fofl $_{\text {OF }}$ decreases linearly from $\mathrm{F}_{\text {MSY }}$ to $\mathrm{F}_{\mathrm{MSY}} \cdot(\beta-\alpha) /(1-\alpha)$ as B decreases from $\mathrm{B}_{\text {MSY }}$ to $\beta \cdot$ B $_{\text {MSY }}$
- When $\mathrm{B} \leq \beta \cdot \mathrm{B}_{\text {MSY }}, \mathrm{F}=0$ for the directed fishery and $\mathrm{F}_{\mathrm{OFL}} \leq \mathrm{F}_{\text {MSY }}$ for the non-directed fisheries, which will be determined in the development of the rebuilding plan.
- The parameter, $\beta$, determines the threshold level of $B$ at or below which directed fishing is prohibited.
- The parameter, $\alpha$, determines the value of $\mathrm{F}_{\text {OFL }}$ when B decreases to $\beta \cdot \mathrm{B}_{\text {MSY }}$ and the rate

- Larger values of $\alpha$ result in a smaller value of $F_{\text {OfL }}$ when $B$ decreases to $\beta \cdot B_{\text {MSY }}$.
- Larger values of $\alpha$ result in Fofl decreasing at a higher rate with decreasing values of B when $\beta \cdot \mathrm{B}_{\text {MSY }}<\mathrm{B} \leq \mathrm{B}_{\text {MSY }}$.
- The parameter, $\mathrm{b}_{\mathrm{y}}$, is the value for the annual buffer calculated from a $\mathrm{P}^{*}$ of 0.49 and a probability distribution for the OFL that accounts for scientific uncertainty in the estimate of OFL.
- $P^{*}$ is the probability that the estimate of ABC , which is calculated from the estimate of OFL, exceeds the "true" OFL (noted as OFL') (P(ABC>OFL').

## Crab Plan Team Recommendations

Table 3 lists the team's recommendations for 2018/2019 on Tier assignments, model parameterizations, time periods for reference biomass estimation or appropriate catch averages, OFLs and ABCs. The team recommends four stocks be placed in Tier 3 (EBS snow crab, Bristol Bay red king crab, EBS Tanner crab and Aleutian Island golden king crab), four stocks in Tier 4 (St. Matthew blue king crab, Pribilof Islands blue king crab, Pribilof Islands red king crab, and Norton Sound red king crab) and two stocks in Tier 5 (Pribilof Islands golden king crab, and Adak red king crab). Table 4 lists those stocks for which the team recommends an ABC less than the maximum permissible ABC for 2018/19. Stock status in relation to status determination criteria are evaluated in this report (Table 5). Status of stocks in relation to status determination criteria for stocks in Tiers 3 and 4 are shown in Figure 2. EBS Tanner crab and Aleutian Islands golden king crab are estimated to be above $B_{M S Y}$ for 2018/19 while EBS snow crab, Bristol Bay red king crab, Pribilof Island red king crab and Norton Sound red king crab are estimated below $B_{M S Y}$. Saint Matthew blue king crab is estimated to be below MSST while Pribilof Islands blue king crab stock remains overfished and estimated to be well below its MSST.

The CPT has general recommendations for all assessments and specific comments related to individual assessments. All recommendations are for consideration for the next scheduled assessment. The general comments are listed below while the comments related to individual assessments are contained within the summary of CPT deliberations and recommendations contained in the stock specific summary section. Additional details regarding recommendations are contained in the Crab Plan Team Report (September 2018 CPT Report).

## General Recommendations for all Assessments

1. The CPT recommends that all assessment authors document assumptions and simulate data under those assumptions to test the ability of the model to estimate key parameters in an unbiased manner. These simulations would be used to demonstrate precision and bias in estimated model parameters.
2. The CPT recommends that weighting factors be expressed as sigmas or CVs or effective sample sizes. The team requests all authors to follow the Guidelines for SAFE preparation and to follow the Terms of Reference as listed therein as applicable by individual assessment for both content and diagnostics.
3. Authors should focus on displaying information on revised models as compared to last year's model rather than focusing on aspects of the assessment that have not changed from the previous year.
4. The current approach for fitting length-composition data accounts for sampling error but ignores the fact that selectivity among size classes is not constant within years; a small change in the selectivity on small animals could lead to a very large change in the catch of such animals. Authors are encouraged to develop approaches for accounting for this source of process error. This issue is generic to assessments of crab and groundfish stocks.
5. Authors are reminded that assessments should include the time series of stock estimates at the time of survey for at least the author's recommended model in that year.
6. Consider stepwise changes to data as individual model runs instead of changing multiple parameters at once so that changes in model performance may be attributed to specific data

By convention the CPT used the following conversions to include tables in both lb and t in the status summary sections:

- million lb to 1000 t [/2.204624]
- 1000 t to million lb [/0.453592]

## Stock Status Summaries

## 1 Eastern Bering Sea Snow crab

## Fishery information relative to OFL setting

Total catch mortality in 2017/18 was 10,500 t (with discard mortality rates applied), while the retained catch in the directed fishery was $8,600 \mathrm{t}$. This was below the $2017 / 18$ OFL of $28,400 \mathrm{t}$. Snow crab bycatch occurs in the directed fishery and to a lesser extent in the groundfish trawl fisheries. Estimates of trawl bycatch in recent years are less than $1 \%$ of the total snow crab catch. Estimates of stock status were above the $B_{M S Y}$ proxy for this stock $\left(B_{35 \%}\right)$ in $2010 / 11-2012 / 13$, but below the $B_{M S Y}$ proxy more recently. For $2018 / 19$, the ratio of projected $\mathrm{MMB}(123.1 \mathrm{t})$ fishing at the $\mathrm{F}_{\mathrm{OFL}}$ to $B_{M S Y}(142,800 \mathrm{t})$ remains less than 1 but above 0.5 .

## Data and assessment methodology

The stock assessment is based on a size- and sex-structured model in which crabs are categorized into immature or mature and new or old shell. The model is fitted to abundance and size frequency data from the NMFS trawl survey, total catch data from the directed fishery, bycatch data from the trawl fishery, size frequency data for male retained catch in the directed fishery, and male and female bycatch in the directed and trawl fisheries. The model is also fitted to biomass estimates and size frequency data from the 2009 and 2010 BSFRF surveys. Updated data in the model include biomass and length frequency data from the 2018 NMFS Eastern Bering Sea trawl survey, retained and discard catch and length frequencies from the 2017/18 directed fishery, and discard catch and length frequencies from the 2017/18 groundfish fisheries.

The model estimation structure is essentially identical to the 2017 assessment. A jittering approach within a maximum likelihood framework was used to evaluate model stability, and retrospective analysis was used as an additional model diagnostic. All model configurations exhibit some degree of model instability and retrospective patterns, but some model configurations were better than others.

The assessment author examined eight model runs. Model "New Data" was the 2017 final model with the new data. Model "Fix fem M" fixed mature female $M$ at $0.23 \mathrm{yr}^{-1}$ as in 2016 assessment rather than estimating it with an informative prior. Model "Loose prior M" estimated all natural mortalities with a looser prior on $M$. Model "Looser prior M" estimated all natural mortalities with an even looser prior on M. Model "Sep devs" was similar to "New Data:, except separate recruitment deviations were estimated for females and males Model "Sep devs + Loose prior $M$ " estimated separate recruitment deviations for females and males with a loose prior on $M$. Model "Sep devs + Looser prior M": estimated separate recruitment deviations for females and males with a looser prior on $M$. The final model was "Sep devs + Loose prior $M+$ Growth", which estimated separate recruitment deviations for females and males with a loose prior on $M$ and assumed a linear relationship between growth increment and pre-molt size.

The CPT selected model "Sep devs" because estimating separate recruitment deviations for males and females led to better fits to the survey biomass estimates and improved retrospective patterns. The CPT did not support the models based on loose and looser $M$ priors owing to a lack of basis for the assumed priors.

## Stock biomass and recruitment trends

Survey mature male biomass based on a maturity ogive decreased from 167,100 t in 2011 to $97,500 \mathrm{t}$ in 2013 , increased to $163,500 \mathrm{t}$ in 2014, fell to $63,200 \mathrm{t}$ in 2016, and increased to $84,000 \mathrm{t}$ in 2017 and

198,400t in 2018. The 2018 survey mature male biomass is the largest since 1998. The 2018 model estimates of mature male biomass showed trends similar to survey biomass during 2011-2018, except that the model failed to match the 1 -year spike in survey biomass observed in 2014 and was unable to match the high 2018 estimate. Observed survey mature female biomass rose quickly from 52,200 t in 2009 to $175,800 \mathrm{t}$ in 2011, its highest value since 1991, decreased steadily to $55,400 \mathrm{t}$ in 2016, then increased to $106,800 \mathrm{t}$ in 2017 and to $165,900 \mathrm{t}$ in 2018. Compared to the 2016 assessment, the model fits the abundance estimates quite closely from 2010. The increase in biomass is driven by high estimates of recruitment for 2014/15.

## Tier determination/Plan Team discussion and resulting OFL/ABC determination Status and catch specifications

The CPT recommends that the EBS snow crab is a Tier 3 stock so the OFL will be determined by the $\mathrm{F}_{\text {OFL }}$ control rule using $\mathrm{F}_{35 \%}$ as the proxy for $\mathrm{F}_{\mathrm{MSY}}$. The proxy for $B_{M S Y}\left(B_{35 \%}\right)$ is the mature male biomass at mating ( 142.8 thousand $t$ ) based on average recruitment over 1982 to 2017. Consequently, the minimum stock size threshold (MSST) is 71.4 thousand t . The CPT recommends that the ABC be less than maximum permissible ABC. The CPT recommends continuing the buffer of $20 \%$ adopted during 2017 for setting the 2018/19 ABC. This level of buffer is justified given the continuing concerns about model misspecification and parameter confounding, the ongoing evidence for retrospective patterns, and model instability even for the CPT-preferred model.

## 2 Bristol Bay Red King Crab

## Fishery information relative to OFL setting

The commercial harvest of Bristol Bay red king crab (BBRKC) dates to the 1930s. The fishery was initially prosecuted mostly by foreign fleets but shifted to a largely domestic fishery in the early 1970s. Retained catch peaked in 1980 at 129.9 million lb ( 58.9 thousand t , but harvests dropped sharply in the early 1980s, and population abundance has remained at relatively low levels over the last two decades compared to those seen in the 1970s. The fishery is managed for a total allowable catch (TAC) coupled with restrictions for sex (males only), a minimum size for legal retention ( $6.5-\mathrm{in}$ carapace width; $135-\mathrm{mm}$ carapace length is used a proxy for 6.5 -in carapace width in the assessment), and season (no fishing during mating/molting periods). In addition to the retained catch that occurs during the commercial fishery, which is limited by the TAC, there is also retained catch that occurs in the ADF\&G cost-recovery fishery.

The current SOA harvest strategy allows a maximum harvest rate of $15 \%$ of mature-sized ( $\geq 120 \mathrm{~mm} \mathrm{CL}$ ) males, but also incorporates a maximum harvest rate of $50 \%$ of legal males and a threshold of 8.4 million mature-sized ( $\geq 90 \mathrm{~mm} \mathrm{CL}$ ) females and 14.5 million lb ( 6.6 thousand t ) of effective spawning biomass (ESB), to prosecute a fishery. Annual non-retained catch of female and sublegal male RKC during the fishery averaged less than 3.9 million lb ( 8.6 thousand t ) since data collection began in 1990. Total catch (retained and bycatch mortality) increased from 16.9 million lb ( 7.6 thousand t ) in 2004/05 to 23.4 million lb ( 10.6 thousand t ) in 2007/08 but has decreased since then; retained catch in 2017/18 was 6.82 million lb ( 3.09 thousand t ) and total catch mortality was 7.67 million lb ( 3.48 thousand t ).

## Data and assessment methodology

The stock assessment is based on a sex- and size-structured population dynamics model incorporating data from the NMFS eastern Bering Sea trawl survey, the Bering Sea Fisheries Research Foundation (BSFRF) trawl survey, landings of commercial catch, at-sea observer sampling, and dockside retained catch sampling. In the model recommended by the CPT, annual stock abundance was estimated for male and female crabs $\geq 65-\mathrm{mm}$ carapace length from 1975 to the time of the 2018 survey and mature male (males $\geq 120 \mathrm{~mm}$ CL) biomass was projected to 15 February 2019. 2017/18 fishery catch data on retained catch in the directed fishery were obtained from ADF\&G fish tickets and reports (retained catch numbers, retained catch weight, and pot lifts by statistical area and landing date), on bycatch in the red king crab and Tanner crab fisheries from the ADF\&G observer database, and on bycatch in the groundfish trawl fisheries from the NMFS groundfish observer database. The 1975-2017 NMFS trawl survey dataset was updated with data from the 2018 survey, including sex-specific area-swept estimates of abundance, biomass, and size composition. The 2018 survey biomass estimate for mature males was the lowest since 1982.

Changes to the basic model methods included: (1) correcting to two minor coding errors that overweighted size compositions in the NMFS surveys at small sizes and under-weighted BSFRF survey biomass when minimizing the model's objective function during parameter optimization, (2) dropping the terminal year recruitment estimate from the time period determining average recruitment in the calculation for $\mathrm{B}_{\mathrm{MSY}}$ (as agreed at the May 2018 CPT meeting), and (3) fitting to observer-estimated total catch biomass and size compositions in the directed fishery instead of discarded male biomass and size compositions. For all scenarios, the BSFRF survey was assumed to capture all crab in the path of the net (i.e., the "capture probability" was 1 for all length groups). As a consequence, the BSFRF survey sex- and size-specific selectivities were identical to the availability of crab by sex and length bin and NMFS survey selectivities were simply the product of the estimated BSFRF survey selectivities (crab availabilities) and
the NMFS survey capture probabilities. Additionally, bycatch in the groundfish fisheries in this scenario was separated into trawl and fixed gear fisheries.

Six model scenarios were evaluated for the 2018 assessment. Scenario " 2 b -old" was identical to Scenario 2 b from the 2017 assessment and included the two coding errors noted above. The purpose of this scenario was to provide a basis for assessing the impact of the coding corrections on the model going forward, as well as to the 2017 assessment. Scenario " 2 b " in the 2018 assessment included the corrections to the two coding errors but was otherwise identical to Scenario $2 b$-old. Scenario " 18.0 " was similar to Scenario 2b, except that: (1) it fit observer-estimated total male catch biomass and size compositions in the directed fishery (replacing fits to discarded male biomass and size compositions), (2) estimated sizedependent curves reflecting male total catch selectivity and proportion retained (replacing curves reflecting retained selectivity and discarded male selectivity), and (3) estimated different logistic curves reflecting the proportion retained in the period before, and in the period after, rationalization in 2005 to account for potential differences in the degree of high-grading in the two periods, under the assumption that all fully-selected animals were retained. Scenario " 18.0 a " represented a minor variation on 18.0 in which the same annual effective sample sizes were the same for male and female length compositions (whereas they could be different in 18.0). Scenario " 18.0 b" was similar to 18.0 , except that only one logistic curve was estimated to characterize retained proportions but annual factors for the maximum proportion retained were estimated for the post-rationalization period 2005-current to capture changes in high-grading. Finally, Scenario " 18.0 c " was similar to 18.0 b, except that one logistic curve was estimated for male total selectivity in the directed fishery but with annual deviations in the length-at-50\% selected while another was estimated for retained proportions, but with annual deviations for the length-at- $50 \%$ retained after 2004.

The CPT selected model scenario 18.0a as its recommended model for status determination and OFL setting. Results from all scenarios were quite similar, and all of the models overpredicted the very low 2018 NMFS survey biomass. The CPT noted that similar lacks of fit have been found previously when survey biomass dropped suddenly, reflecting uncertainty in whether the underlying cause was a change in availability or mortality (i.e., the "hide 'em/kill 'em" uncertainty). The effect of the coding errors on model results was small, but the former problematic estimate of $\mathrm{Q}=1$ for the NMFS survey was eliminated (estimated Q's were $\sim 0.92$ ). Scenario 2 b-old fit the NMFS survey data slightly better than the other scenarios but this was a result of it mistakenly overweighting the NMFS survey length compositions at small sizes and underweighting the BSFRF survey biomass. Scenario 2b, fitting to discard catch biomass and size compositions, can not be carried forward because at-sea crab observers will no longer predict which crab will be discarded. While all scenarios fit the retained catch and total catch biomass data similarly well, the estimated total male catch biomass in the directed fishery showed some odd variability in Scenario 18.0c when it extrapolated the available data, which starts in 1990/91, into the past back to 1975 . The CPT rejected Scenario 18.0 on a technical issue because it incorrectly assigned different effective annual sample sizes to male and female size compositions when calculating the model likelihood. The CPT thus selected Scenario 18.0a for status determination and OFL setting on the basis that it was technically correctly on the issue of sample sizes for size compositions and exhibited similar fits to the data while being more parsimonious than Scenario 18.0 b (i.e., having fewer parameters).

## Stock biomass and recruitment trends

Based on the CPT-recommended scenario, 18.0a, the MMB at the time of mating is estimated to have been highest early in the late 1970s (approximately 111 thousand t), with secondary peaks in 1989 (28 thousand $t$ ) and 2002-3 and 2010-11 ( $\sim 31$ thousand $t)$. The estimated MMB at time of mating in 2017/8 was 24.86 thousand $t$, the lowest in 1998 ( 23.41 thousand $t$ ). The projection for the 2018/19 time of mating, which assumes the fishing mortality in 2018/19 matches that corresponding to the OFL, is 20.80 thousand $t$. Estimates of recruitment since 1985 have been generally low relative to those estimated for
the period prior to 1985 and intermittent peaks in 1995, 2002, and 2005 ( 56,53 , and 43 million crab, respectively). The relatively low recruitment estimate of 14.6 million crab for 2018 was, however, the largest since 2011 ( 16.0 million crab).

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

Bristol Bay red king crab is in Tier 3. Based on the author's discussion regarding an apparent reduction in stock productivity associated with the 1976/77 climate regime shift in the EBS, the CPT recommends computing average recruitment as has been done in recent assessments (i.e., based on model recruitment using the time period 1984 (corresponding to fertilization in 1977) to the penultimate year of the assessment. Following discussions on the topic at the January and May 2018 CPT meetings, the CPT concurred with the author's recommendation to drop the terminal year recruitment from the time period for average recruitment because it is highly uncertain. The estimated $B_{35 \%}$ is 25.5 thousand t . MMB projected for $2018 / 19$ is 20.80 thousand $\mathrm{t}, 82 \%$ of $B_{35 \%}$. Consequently, the BBRKC stock is in Tier 3 b in 2018/19.

The CPT recommends that the OFL for 2018/19 be set according to model scenario 18.0a, for which the calculated OFL is 5.34 thousand $\mathrm{t}(11.76$ million lb). Given the inability of the model to adequately fit the 2018 survey biomass, the team recommends that the ABC for 2018/19 be set below the maximum permissible ABC. The team recommends that a $20 \%$ buffer from the OFL be used to set the ABC at 4.27 thousand t ( 9.41 million lb ). In previous assessments, a $10 \%$ buffer has been applied to the OFL to set ABC , but the CPT feels that the rather unusual environmental conditions in the EBS this year (e.g., elevated bottom temperatures, lack of a cold pool) and the model's poor fit to the 2018 survey data increase the uncertainty associated with this stock and warrant additional precaution.

MMB for 2017/18 was estimated to be 24.86 thousand $t$ and above MSST ( 12.74 thousand $t$ ); hence the stock was not overfished in 2017/18. The total catch in 2017/18 ( 3.48 thousand t) was less than the 2017/18 OFL ( 5.60 thousand $t$ ); hence overfishing did not occur in 2017/18. The stock at 2018/19 time of mating is projected to be above the MSST and $82 \%$ of $B_{35 \%}$ (see above); hence the stock is not approaching an overfished condition in 2018/19.

## 3 Eastern Bering Sea Tanner crab

## Fishery information relative to OFL setting

Eastern Bering Sea (EBS) Tanner crab are caught in directed Tanner crab fisheries, as bycatch in the groundfish fisheries, scallop fisheries, as bycatch in the directed Tanner crab fishery (mainly as nonretained females and sublegal males), and other crab fisheries (notably, eastern Bering Sea snow crab and, to a lesser extent, Bristol Bay red king crab). A single OFL is set for Tanner crab in the EBS. Under the Crab Rationalization Program, ADF\&G sets separate TACs for directed fisheries east and west of $166^{\circ} \mathrm{W}$ longitude. The mature male biomass was estimated to be below the Minimum Stock Size Threshold ( $0.5 B_{\text {мsy }}$ ) in February 2010 (the assumed time of mating) based on trends in mature male biomass from the survey, and NMFS declared the stock overfished in September 2010. The directed fishery was closed from 2010/11 through 2012/13 crab fishery years.

NMFS determined the stock was not overfished in 2012 based on a new assessment model with a revised estimate of $B_{\text {msy. }}$. The directed fishery was open for the 2013/14 to 2015/16 seasons with a total allowable catch (TAC) of $1,410 \mathrm{t}$ in 2013/14, 6,850 t in 2014/15, and $8,920 \mathrm{t}$ in 2015/16. The total retained catch in 2015/16 (8,910 t) was the largest taken in the fishery since 1992/93. In 2016/17, ADF\&G determined that mature female biomass did not meet the criteria for opening a fishery according to the regulatory harvest strategy, and the TAC was set at zero. Consequently, there was no directed harvest in 2016/17. In 2017/18, ADF\&G determined that a directed fishery could occur in the area west of $166^{\circ} \mathrm{W}$ longitude. The TAC was set at $1,130 \mathrm{t}$, of which $100 \%$ was taken.

## Data and assessment methodology

The SSC accepted a size-structured assessment model for use in harvest specifications in 2012 and classified the EBS Tanner stock as a Tier 3 stock. This year's assessment used a new modeling framework, TCSAM02, which was endorsed by the SSC in June 2017. TCSAM02 is similar to previous Tanner crab assessment models but includes improvements to the modeling of fishery and population processes. The model is structured by crab size, sex, shell condition, and maturity. The model uses available data on quantity and size-composition from: the NMFS trawl survey; landings and discards by the directed fishery; bycatch in the Bristol Bay red king crab, EBS snow crab, and groundfish fisheries. The model includes prior distributions on parameters related to natural mortality and catchability, and penalties on changes in recruitment and in the proportion maturing. Input data sets were updated with the most recent information, including the NMFS EBS trawl survey in 2018; bycatch, and size composition data from the 2017/18 crab fisheries; and data on Tanner crab bycatch in the groundfish fisheries in 2017/18.

The model recommended by the CPT to set the OFL and the ABC is a model with last year's configuration that was fully updated with recent survey and fishery data. The CPT identified several concerns with new models presented in the assessment. The most important of these concerns was that all of the new models used a revised catch estimates in the directed fishery and the bycatch in snow crab fish. These estimates were nearly the same as the original estimates after 1995 but showed much larger changes in 1992-1995 (catches prior to 1992 were not revised). Inclusion of these revised catch estimates had a large impact on estimated Tanner crab biomass for the entire time series, shifting it upwards by approximately $70 \%$. CPT was concerned that there was no opportunity to review the methodology to produce the new estimates, and it was unclear to the CPT whether observer coverage (the basis for the revised catch estimates) was adequate to support earlier estimates. Second, the revised catch time series was only used for Tanner crab and not for the other crab assessments in this cycle. The CPT would have preferred that revisions to catch estimates be done consistently for all crab stocks, rather than in a
piecemeal way. Finally, it was not clear to the CPT what was driving the extreme sensitivity of the model to the revised catch estimates.

## Stock biomass and recruitment trends

The MMB at the time of mating is estimated to have been highest early in the early 1970s (approximately 300 thousand t), with secondary peaks in 1989 ( 75 thousand t), $2008-2009$ ( 76 thousand t), and in 2014 ( 83 thousand t ). The estimated MMB at time of mating in 2017/18 was 64.09 thousand t and the projection for the 2018/19 time of mating is 35.95 thousand $t$. Estimates of recruitment since 1999 have been generally low relative to the peaks estimated for the period prior to 1990 . There was a relatively strong recruitment estimated for 2017 and 2018, but these estimates are very uncertain and will need to be confirmed by subsequent assessments.

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

The CPT recommends the OFL for this stock be based on the Tier 3 control rule. Application of the Tier 3 control rule requires a set of years for defining $\mathrm{R}_{M S Y}$, the mean recruitment corresponding to $B_{M S Y}$ under prevailing environmental conditions. The recommended time period for defining average recruitment for determining the BMSY is 1982 - 2018; the 1982-and-onwards time period has been used in previous OFL determination and follows the most-recent recommendation of the SSC.

Based on the estimated biomass at 15 February 2018, the stock is at Tier 3 level a. The $F_{M S Y}$ proxy ( $F_{35 \%}$ ) is $0.74 \mathrm{yr}^{-1}$, and the $2018 / 19$ Fofl is $0.74 \mathrm{yr}^{-1}$ under the Tier 3 level a OFL Control Rule, which results in a total male and female OFL of 20.87 thousand t . The CPT recommends a $20 \%$ buffer to account for model uncertainty and stock productivity uncertainty be applied to the OFL, to set $\mathrm{ABC}=16.70$ thousand t . The $20 \%$ buffer is the same that the SSC recommended for determination of the 2017/18 ABC.

## $4 \quad$ Pribilof Islands red king crab [from the 2017 assessment]

In accordance with the approved schedule, no assessment was conducted for Pribilof Islands red king crab this year, however, a full stock assessment will be conducted in 2019. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018/19 specifications. Additional information listed below summarizes the 2017 assessment.

## Fishery information relative to OFL setting

The Pribilof Islands red king crab fishery began in 1973 as bycatch during the blue king crab fishery. In 1993 and 1994 the red king crab fishery was open to directed fishing, and blue king crab was closed. From 1995 through 1998, combined Pribilof Islands red and blue king crab GHLs were used. Declines in crab abundance of both red and blue king crab stocks from 1996 to 1998 resulted in poor fishery performance with annual harvests below the GHLs. The Pribilof red king crab fishery has been closed since 1999 due to uncertainty in estimated red king crab abundance and concerns for bycatch mortality of blue king crab, which is overfished and severely depressed. Fishery closures near the Pribilof Islands have resulted in low bycatch, recent bycatch has been well below the OFL, ranging from 0.32 to 13.1 t ( $<0.001$ to 0.029 million pounds; 2012/13-2016/17).

## Data and assessment methodology

The 2017 assessment is based on trends in male mature biomass (MMB) at the time of mating inferred from NMFS bottom trawl survey from 1975-2017 and commercial catch and observer data from 1973/74 to 2016/17. Two assessment methods using a Tier 4 harvest control rule were presented for evaluation: one calculated an annual index of MMB derived as the 3 -yr running average using inverse variance weighting, and the second was a random effects model. The random effects model was presented with three variations: 1) $\lambda$ fixed, 2) a prior on $\lambda$ estimated from bootstrap (with $C V=2.24$ ) and 2 ) a prior on $\lambda$ with CV 4.0.

## Stock biomass and recruitment trends

Male and female abundance varies widely over the history of the survey time series and uncertainty around area-swept estimates of abundance are large due to relatively low sample sizes. Recruitment for this stock is generally low and episodic. Numbers at length vary dramatically from year to year; however, two (possibly three) cohorts can be seen moving through the length frequencies over time. $\mathrm{MMB}_{\text {mating }}$ increased over 2012 to 2016. Estimates for the 3-year moving average for $\mathrm{MMB}_{\text {mating }}$ in recent years approached those estimated during the early 1990s, peaking in 2014/15 at 9,963 t ( 21.96 million pounds).

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

The CPT recommended the Tier 4 stock status determination and selected the random effects model with a prior on $\lambda$ estimated from a simple exponential model. A bootstrap analysis was used to obtain a prior $\mathrm{CV}=2.24$. This model was selected because it is a better smoother of extreme survey values. For 2017/18 the $B_{\text {MSY }}=4,604 \mathrm{t}$ ( 10.15 million pounds) derived as the mean $\mathrm{MMB}_{\text {mating }}$ from 1991/92 to 2016/17 from the random effects model. Male mature biomass at the time of mating for $2017 / 18$ was estimated at 3,364 $\mathrm{t}(7.416$ million pounds $)$. The $B / B_{\mathrm{MSY}}=0.73$ and $F_{\mathrm{OFL}}=0.13 . B / B_{\mathrm{MSY} \text { Proxy }}$ is $<1$, therefore the stock status level is Tier $4 b$. For the 2017/17 fishery, the OFL is 482 t ( 1.063 million lb). The CPT recommended a $25 \%$ buffer for an ABC from the OFL as in previous years.

Historical status and catch specifications for Pribilof Islands red king crab (t). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| $2017 / 18$ |  | $7.42^{*}$ | 0 | 0 | $<0.001$ | 1.06 | 0.80 |
| $2018 / 19$ |  |  |  |  |  | $1.06^{*}$ | $0.80^{*}$ |

*Value estimated from the most recent assessment

The stock was above MSST in 2016/17 and was not overfished at the time of the last assessment. Overfishing did not occur during the 2017/18 fishing year.

## $5 \quad$ Pribilof Islands blue king crab

In accordance with the approved schedule, no assessment was conducted for Pribilof Islands blue king crab this year, however, a full stock assessment will be conducted in 2019. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018/19 specifications. Additional information listed below summarizes the 2017 assessment.

Fishery information relative to OFL setting.
The Pribilof Islands blue king crab fishery began in 1973, with peak landings of 11.0 million lb during the 1980/81 season. A steep decline in landings occurred after the 1980/81 season. Directed fishery harvest from 1984/85 until 1987/88 was annually less than 1.0 million lb with low CPUE. The fishery was closed from 1988/89 through 1994/95 fishing seasons. The fishery reopened for the 1995/96 to 1998/99 seasons. Fishery harvests during this period ranged from 1.3 to 2.5 million lb. The fishery closed again for the 1999/00 season due to declining stock abundance and has remained closed to the present.

The stock was declared overfished in 2002 and a rebuilding plan implemented in 2004. The rebuilding plan closed directed fishing for Pribilof blue king crab until the stock was rebuilt. In 2009, NMFS determined the stock would not meet its 10-year rebuilding horizon. Subsequently, Amendment 43 to the King and Tanner Crab FMP and Amendment 103 to the BSAI Groundfish FMP were approved by the Secretary of Commerce in 2014. This action, a revised rebuilding plan, closed the Pribilof Island Habitat Conservation Zone to Pacific cod pot fishing, which accounts for the highest recent rates of bycatch of this stock. This area was already closed to groundfish trawl fishing. To prevent overfishing in the future, $\mathrm{ADF} \& \mathrm{G}$ will implement closure areas for the commercial crab fisheries to reduce the blue king crab bycatch. NMFS recently implemented a procedure to account for blue king crab bycatch in the groundfish fisheries inseason and will take inseason action to prevent overfishing.

## Data and assessment methodology

The calculation of the 2017/18 survey biomass uses the stock area definition established in 2012/13 that includes an additional 20 nm strip east of the Pribilof District. This assessment uses the 2016/17 methodology to project MMB and calculate $B_{M S Y}$. Prior to 2016/17, MMB for the current year was estimated from the NMFS EBS bottom trawl survey using a three-year running average weighted by the inverse of the variance of the area-swept estimate. The new methodology to calculate MMB and $\mathrm{B}_{\mathrm{MSY}}$ was recommended by the CPT and uses a random effects model to smooth the survey time series. This model smooths the MMB estimates without low abundance estimates having undue influence. Differences in abundance estimates from the two methods were largest during periods of high interannual variability. Differences between the methods were small in recent years. Results from this method are shown starting with the 2015/16 MMB and 2016/2017 projected MMB.

## Stock biomass and recruitment trends

The $2017 / 18$ MMB at mating is projected to be 230 t , which is approximately $6 \%$ of the proxy for $B_{M S Y}$. The Pribilof blue king crab stock biomass continues to be low with no indication of recruitment.

Tier determination/Plan Team discussion and resulting OFL and ABC determination
This stock is recommended for placement into Tier 4. $B_{M S Y}$ was estimated using the time periods 1980/81 -1984/85 and 1990/91-1997/98. This range was chosen because it eliminates periods of extremely low abundance that may not be representative of the production potential of the stock. $B_{M S Y}$ is estimated at $4,108 \mathrm{t}$ ( 9.06 million pounds) for 2017/18.

Because the projected 2017/18 estimate of MMB is less than $25 \% B_{M S Y}$, the stock is in stock status c and the directed fishery F is 0 . However, an Fofl must be determined for the non-directed catch. Ideally this should be based on the rebuilding strategy. For this stock the Fofl is based on average groundfish bycatch between 1999/00 and 2005/06. The recommended OFL for $2017 / 18$ is $1.16 \mathrm{t}(0.0026$ million lb).

The CPT recommended setting the ABC less than the maximum permissible by employing a $25 \%$ buffer on the OFL. This recommendation was based upon continuing concerns with stock status and consistency with relative buffer levels for other stocks for which the OFL is based upon average catch.

Historical status and catch specifications for Pribilof Islands blue king crab (t). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | 2,055 | 344 | Closed | 0 | 0.07 | 1.16 | 0.87 |
| $2015 / 16$ | 2,058 | 361 | Closed | 0 | 1.18 | 1.16 | 0.87 |

| $2017 / 18$ |  | $230^{*}$ | Closed |  | 0.33 | 1.16 | 0.87 |
| $2018 / 19$ | Not <br> estimated |  |  |  |  |  |  |

*Value estimated from the most recent assessment
Historical status and catch specifications for Pribilof Islands blue king crab (million lb). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | 4.531 | 0.758 | Closed | 0 | 0.0002 | 0.0026 | 0.002 |
| $2015 / 16$ | 4.537 | 0.796 | Closed | 0 | 0.0026 | 0.0026 | 0.002 |
| $2016 / 17$ | 4.528 | 0.511 | Closed | 0 | 0.0008 | 0.0026 | 0.002 |
| $2017 / 18$ |  | $0.507^{*}$ | Closed | 0 | 0.0007 | 0.0026 | 0.002 |
| $2018 / 19$ |  | Not <br> estimated |  |  |  | $0.0026^{*}$ | $0.002^{*}$ |

*Value estimated from the most recent assessment
The total catch for 2016/17 ( $0.38 \mathrm{t}, 0.0008$ million lb) was less than the 2016/17 OFL ( $1.16 \mathrm{t}, 0.0026$ million lb) so overfishing did not occur during 2016/17. The 2017/18 projected MMB estimate of 230 t $(0.507$ million lb$)$ is below the proxy for $\operatorname{MSST}\left(\mathrm{MMB} / \mathrm{B}_{\mathrm{MSY}}=0.06\right)$ so the stock is projected to continue to be in an overfished condition.

## 6 St. Matthew blue king crab

## Fishery information relative to OFL setting

The fishery was prosecuted as a directed fishery from 1977 to 1998. Harvests peaked in 1983/84 when $4,288 \mathrm{t}$ ( 9.453 million lb) were landed by 164 vessels. Harvest was fairly stable from 1986/87 to 1990/91, averaging $568 \mathrm{t}(1.252$ million lb) annually. Harvest increased to a mean catch of $1,496 \mathrm{t}$ ( 3.298 million lb) during the 1991/92 to 1998/99 seasons until the fishery was declared overfished and closed in 1999 when the stock size estimate was below the MSST. In November 2000, Amendment 15 to the FMP was approved to implement a rebuilding plan for the St. Matthew Island blue king crab stock. The rebuilding plan included a harvest strategy identified in regulation by the Alaska Board of Fisheries, an area closure to control bycatch, and gear modifications. In 2008/09 and 2009/10, the MMB was estimated to be above $B_{\text {MSY }}$ for two years and the stock declared rebuilt in 2009.

The fishery re-opened in 2009/10 with a TAC of $529 \mathrm{t}(1.166$ million lb) and $209 \mathrm{t}(0.461$ million lb) of retained catch were harvested. The 2010/11 TAC was $726 \mathrm{t}(1.601$ million lb$)$ and the fishery reported a retained catch of $573 \mathrm{t}(1.263$ million lb$)$. The $2011 / 12$ harvest of $853 \mathrm{t}(1.881$ million lb) represented $80 \%$ of the $1,152 \mathrm{t}$ ( 2.540 million lb) TAC. In 2012/13, by contrast, harvesters landed $99 \%(733 \mathrm{t}, 1.616$ million lb ) of a reduced TAC of $740 \mathrm{t}(1.630$ million lb$)$, though fishery efficiency, at about 10 crab per pot, was little changed from what it had been in each of the previous three years. The directed fishery was closed in 2013/14 due to declining trawl survey estimates of abundance and concerns about the health of the stock. The directed fishery resumed again in 2014/15 with a TAC of 300 t ( 0.655 million pounds), but the fishery performance was relatively poor with the retained catch of 140 t ( 0.309 million pounds). The TAC in 2015/16 was 190 t ( 0.410 million pounds) with a retained catch of 47 t ( 0.105 million pounds). The fishery has been closed since 2016/17. Bycatch of non-retained blue king crab has occurred in the St. Matthew blue king crab fishery, the eastern Bering Sea snow crab fishery, and trawl and fixed-gear groundfish fisheries. Based on limited observer data, bycatch of sublegal male and female crabs in the directed blue king crab fishery off St. Matthew Island was relatively high when the fishery was prosecuted in the 1990 s, and total bycatch (in terms of number of crabs captured) was often twice as high or higher than total catch of legal crabs.

## Data and assessment methodology

This assessment is conducted in the General Model for Alaska Crab Stocks (GMACS) framework, which was accepted for use by the SSC in June 2016. This assessment differs from the original GMACS model in that natural and fishing mortality are continuous within 5 discrete seasons. In addition, the model estimates a dynamic $B_{0}$ computed as spawning biomass relative to spawning biomass if no fishing harvests had occurred. Season length in GMACS is controlled by changing the proportion of natural mortality that is applied during each season.

The GMACS assesses male crab $\geq 90 \mathrm{~mm}$ CL. The three length categories are: $90-104 \mathrm{~mm} \mathrm{CL}$; 105-119 mm CL ; and $\geq 120 \mathrm{~mm}$ CL. Males $\geq 105 \mathrm{~mm} \mathrm{CL}$ are used as a proxy for mature males, and males $\geq 120$ mm CL are used as a proxy for legal males ( $\geq 5.5$ inch carapace width). The model incorporates the following data: (1) commercial catch data from 1978/79-1998/99, 2009/10-2012/13, 2015/16; (2) annual trawl survey data from 1978 to 2018; (3) triennial pot survey data from 1995 to 2013 and annually from 2015 to 2018; (4) bycatch data in the groundfish trawl and groundfish fixed-gear fisheries from 1991 to 2017; and (5) ADF\&G crab-observer composition data for the years 1990/91-1998/99, 2009/10-2012/13, 2014/15, and 2015/16.

The NMFS summer trawl survey data are from 56 stations within the St. Matthew Island Section whereas the ADF\&G pot survey included 96 stations in 2018. The pot surveys occur during July and August in
areas of high-relief habitat important to blue king crab (particularly females) in areas missed by the NMFS trawl survey. Groundfish discard information for trawl and fixed gear is derived from NMFS observer data for the stock reporting area for SMBKC.

## Stock biomass and recruitment trends

Following a period of low values after the stock was declared overfished in 1999, trawl-survey indices of stock abundance and biomass generally increased to well above average during 2007-2012. In 2013 survey biomass declined ( $\sim 40 \%$ of the mean value) but was followed by average biomass estimates in 2014 and 2015, but with survey CVs of $77 \%$ and $45 \%$, respectively). The 2016 survey biomass fell to $3,485 \mathrm{t}$ ( 7.7 million lb with a CV of $39 \%$ ), followed by continued declines to the 2018 survey estimate of $1,731 \mathrm{t}$ ( 3.816 million lb , with a CV of $28 \%$ ). This value represents $31 \%$ of the long term mean (mean of $5,664 \mathrm{t}$ during 1978-2018) with the most recent 3 -year average surveys at $41 \%$ of the historical mean, again indicating a general decline in biomass since 2010.

Because little information about the abundance of small crab is available for this stock, recruitment has been assessed in terms of the number of male crab within the $90-104 \mathrm{~mm}$ CL size class in each year. The 2018 trawl-survey area-swept estimate of 0.154 million males in this size class is the third lowest in the 41 -year time series since 1978 and only $15 \%$ of the long-term average recruitment. The 2018 abundance of this size group was also the lowest in the pot survey time series and $10 \%$ of the time series average.

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

The stock assessment examines five model configurations: (1) 2017 Model - the 2017 recommended model without any new data added; (2) BTS - Model 1 with 2018 bottom trawl survey (BTS) data; (3) BTS and pot, "reference model" - Model 2 with 2018 ADFG pot survey data; (4) VAST - a geo-spatial delta-GLMM model to the BTS data; and not run in GMACS; and (5) Fit survey - an exploratory scenario that revises the reference model by reweighting the NMFS trawl and ADF\&G pot surveys by 2.0.

The CPT concurs with the author's recommendation to use the reference case model for the 2018/19 crab year. This stock is in Tier 4. The CPT recommended model uses the full assessment period (1978/79$2017 / 18$ ) to define the proxy for $B_{\mathrm{MSY}}$ in terms of average estimated $M M B_{\text {mating }}$. The projected MMB estimated for 2018/19 under the recommended model is $1,310 \mathrm{t}\left(2.890\right.$ million lb) and the $F_{M S Y}$ proxy is the natural mortality rate ( $0.18^{-1}$ year) and Foft is 0.09 , resulting in a mature male biomass OFL of 04 t ( 0.80 million lb ). The MMB/B $\mathrm{B}_{\text {MSY }}$ ratio is 0.35 . The author recommended and the CPT concurred with a $20 \%$ buffer on the OFL for the ABC which was consistent with the approach used last year. The ABC based on this buffer is $30 \mathrm{t}(0.07$ million lb).

Historical status and catch specifications for Saint Matthew blue king crab (thousand t). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

Historical status and catch specifications for Saint Matthew blue king crab (million lb). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| Year | MSST | Biomass <br> $\left(\right.$ MMB $\left._{\text {mating }}\right)$ | TAC | Retained <br> Catch | Total Male <br> Catch | OFL | ABC |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | 4.1 | 5.47 | 0.655 | 0.309 | 0.329 | 0.94 | 0.75 |
| $2015 / 16$ | 4.0 | 4.65 | 0.41 | 0.105 | 0.105 | 0.62 | 0.49 |
| $2016 / 17$ | 4.30 | 4.91 | 0.00 | 0.000 | 0.000 | 0.31 | 0.25 |
| $2017 / 18$ | 4.1 | 2.85 | 0.00 | 0.000 | 0.000 | 0.27 | 0.22 |
| $2018 / 19$ |  | 2.89 |  |  |  | 0.08 | 0.07 |

The stock was below MSST in 2017/18. Total catch was less than the OFL in 2017/18 and hence overfishing did not occur. The CPT discussed information that will be needed to develop a rebuilding plan if the stock is declared overfished.

## $7 \quad$ Norton Sound red king crab

## Fishery information relative to OFL setting

This stock supports three main fisheries: summer commercial, winter commercial, and winter subsistence. The summer commercial fishery, which accounts for the majority of the catch, reached a peak in the late 1970s at a little over 2.9 million pounds retained catch. Retained catches since 1982 have been below 0.5 million pounds, averaging 0.3 million pounds, including several low years in the 1990s. As the crab population rebounded, retained catches have increased to around 0.5 million pounds in recent years.

## Data and assessment methodology

Four types of surveys have occurred periodically during the last three decades: summer trawl, summer pot, winter pot, and preseason summer pot, but none of these surveys have been conducted every year. The assessment is based on a male-only length-based model of male crab abundance that combines multiple sources of data. A maximum likelihood approach was used to estimate abundance, recruitment, and selectivity and catchability of the commercial pot gear. The model has been updated to include the following data: total catch, catch length composition, discard length composition data from the 2017 summer commercial fishery, and 2016/17 winter commercial and subsistence catch. New trend data in the assessment included 2017 ADFG and NMFS surveys in Norton Sound. In addition, the standardized commercial catch CPUE indices were updated to include data for 1977-2017. The current model assumes a constant $M=0.18 \mathrm{yr}^{-1}$ for all length classes except the $124-133 \mathrm{~mm}$ and the $>134 \mathrm{~mm}$ CL length-classes, which had an estimated value of $0.579 \mathrm{yr}^{-1}$. Logistic functions are used to describe fishery and survey selectivities, except for a dome-shaped function examined for the winter pot fishery.

The assessment author summarized five model run alternatives, a base model (model 0) identical to last year's assessment model, and several models that changed fisheries selectivity and added in estimation of natural mortality for the largest size classes in various ways (models 3, 4, and 5). A final model, model 6, included summer pot survey data. The CPT selected the base model (model 0) as the recommended model. This is also the author's recommended model. This model is also the same configuration as last year's assessment model. Several other models presented in the assessment improved model fits, but the model outputs such as fishery selectivity and estimated natural mortality were considered implausible and thus these models were not regarded as improvements by the CPT.

## Stock biomass and recruitment trends

Mature male biomass was estimated to be at an historic low in 1982 following a sharp decline from the peak biomass in 1977. The MMB then exhibited an increase from a low in 1997 to a peak in 2010, before showing minor declines and increases close to the $B_{M S Y}$ proxy. The stock is current estimated to be on a downward trend. Estimated recruitment was weak during the late 1970s and high during the early 1980s, with a slight downward trend from 1983 to 1993 . Estimated recruitment has generally been variable, with a slight decrease in the last several years.

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

The team continues to recommend Tier 4 for Norton Sound red king crab. The $B_{M S Y \text { proxy }}$, calculated as the average of mature male biomass on February 1 during 1980-2018 was 4.818 million lb. The estimated 2018 mature male biomass on February 1 using Model 0 is 4.079 million lb., which is below the $B_{M S Y}$ proxy for this stock, placing Norton Sound red king crab in status category 4 b .

The $\mathrm{F}_{M S Y \text { proxy }}$ is $M=0.18 \mathrm{yr}^{-1}$ and the $\mathrm{F}_{\text {OFL }}=0.15 \mathrm{yr}^{-1}$, because the 2018 mature male biomass is less than $B_{M S Y}$ proxy, with the CPT choosing the default of gamma $=1.0$.

The CPT recommends that the OFL for 2018 be set according to model 0 , for which the calculated OFL is 0.43 million lb. ( 0.20 thousand t ). The team recommends that the ABC for 2018 be set below the maximum permissible ABC. The team recommends that the SSC endorsed buffer of $20 \%$ from the OFL be used to set the ABC at 0.35 million lb. ( 0.16 thousand t ). The OFL is retained catch OFL although a total catch OFL is computed as part of the assessment. The recommendation of an ABC less than the maximum permissible is due to concerns with model specification and unresolved competing hypotheses about whether the lack of large animals in catches and surveys is due to higher mortality or migration from the area.

Status and catch specifications (1000 t) for Norton Sound red king crab. Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| Year | MSST | Biomass <br> (MMB) | GHL | Retained <br> Catch $^{\mathbf{1}}$ | Total Catch $^{2}$ | Retained <br> Catch <br> OFL | Retained <br> catch <br> ABC |

| 2017 | 1.05 | 2.33 | 0.23 | 0.22 | 0.24 | 0.30 | 0.24 |
| 2018 | 1.09 | 1.85 | TBD | TBD | TBD | 0.20 | 0.16 |

1: Summer commercial fishery
2: Summer commercial fishery, winter commercial fishery and subsistence fishery
Status and catch specifications (million lb.) for Norton Sound red king crab. Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| Year | MSST | Biomass <br> $($ MMB $)$ | GHL | Retained <br> Catch $^{\mathbf{1}}$ | Total <br> Catch $^{2}$ | Retained <br> Catch <br> OFL | Retained <br> catch <br> ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | 2.11 | 3.71 | 0.38 | 0.39 | 0.39 | 0.46 | 0.42 |
| 2015 | 2.41 | 5.13 | 0.39 | 0.40 | 0.52 | 0.72 | 0.58 |
| 2016 | 2.26 | 5.87 | 0.52 | 0.51 | 0.52 | 0.71 | 0.57 |
| 2017 | 2.31 | 5.14 | 0.50 | 0.49 | 0.50 | 0.67 | 0.54 |
| 2018 | 2.41 | 4.08 | TBD | TBD | TBD | 0.43 | 0.35 |

Total retained catch during 2017 did not exceed the OFL for this stock, thus overfishing is not occurring. Stock biomass is above MSST; thus, the stock is not overfished.

## Additional Plan Team recommendations

The CPT has the following recommendations for the next assessment:

- Evaluate methods to improve ADFG bottom trawl survey biomass estimation, including modelbased approaches.
- Quantitatively evaluate the representativeness of observer sampling.
- Estimate a fishery retention curve. Consider alternative (2-parameter and 1-parameter) curves for both retention and selectivity.
- Provide Tier 3 calculations for Norton Sound red king crab and evaluate its suitability for tier 3 status.

## 8 Aleutian Islands Golden King Crab

## Fishery information relative to OFL setting

The directed fishery has been prosecuted annually since the 1981/82 season. Retained catch peaked in 1986/87 at 14.7 million lb and averaged 11.9 million lb over the 1985/86-1989/90 seasons. Average harvests dropped sharply from 1989/90 to 1990/91 to a level of 6.9 million lb for the period 1990/911995/96. Management based on a formally established GHL began with the 1996/97 season. The 5.9 million lb GHL established for the 1996/97 season, which was based on the previous five-year average catch, was subsequently reduced to 5.7 million lb beginning in 1998/99. The GHL (or TAC, since 2005/06) remained at 5.700 million lb for 2007/08 but was increased to 5.985 million lb for the 2008/09-2011/12 seasons, and to 6.290 million lb starting with the 2012/13 season. The TAC was reduced to 5.545 million lb for the 2016/17 season. This fishery is rationalized under the Crab Rationalization Program.

Total mortality of AI golden king crab includes retained catch in the directed fishery, mortality of discarded catch, and bycatch in fixed-gear and trawl groundfish fisheries, though bycatch in other fisheries is low compared to mortality in the directed fishery. Retained catch in the post-rationalized fishery (2005/062016/17) has ranged from 5.245 million lb in 2006/07 to 6.378 million lb in 2013/14. Total mortality ranged from 5.426 to 6.803 million lb for the same period.

## Data and assessment methodology

The assessment for AI golden king crab establishes a single OFL and ABC for the whole stock however separate models are evaluated for EAG and WAG owing to different abundance trends in each area. A modeling framework for AI golden king crab was under development for a number of years, with model assumptions and data inputs refined by reviews by the SSC and CPT. The modeling framework was recommended by the CPT in September 2016 and approved by the SSC in October 2016 for use in the 2017/18 specifications cycle.

The model-based stock assessment involves fitting male-only population dynamics models to data on catches and discards in the directed fishery, discards in the groundfish fishery, standardized indices of abundance based on observer data, fish ticket CPUE data, length-frequency data for the directed fishery (landing and total catch), and mark-recapture data. These data are available through the 2016/17 season.

The assessment author examined seven model scenarios for EAG and six model scenarios for WAG in this assessment. Model 17_0 is the base model, which is the model for last year updated with new data. Model 17_0a used an abundance index from a VAST analysis of CPUE data rather than the standard GLM approach. Model 17_0b used an abundance index from a GLM analysis that uses AIC rather than $r^{2}$ for model selection. Model 17_0c used an abundance index from a GLM analysis that includes year-area interaction terms in the CPUE analysis. Model 17_0d added a third catchability and selectivity period for 2013-2016. Model 17_0e used the McAllister and Ianelli method for tuning the length composition data rather than the Francis method. Model 17_0f included an abundance index from a GLM analysis of the three years of collaborative pot survey data. This index was only evaluated in the EAG model because the survey is conducted only in EAG.

The CPT identified technical issues with each of the new model scenarios that would prevent them from being used for management advice. It is important to note that several of the model scenarios show promise and could potentially be used after additional development and review. The CPT recommends adopting the base model 17_0 for harvest projections.

This is the only crab assessment that relies solely on fishery CPUE as an index of abundance, with the CPUE index standardization process subject to past CPT and SSC review. The CPT recommended that the
model be used to provide management reference points based on the Tier 3 control rule in January 2017 and this tier recommendation was endorsed by the SSC in February 2017.

An industry-ADF\&G collaborative survey has been conducted for this stock during 2015-2017. A preliminary model using an index from this survey was evaluated in the assessment, however additional index development is needed before this model is suitable to provide management advice.

## Stock biomass and recruitment trends

Estimated mature male biomass (MMB) for the EAG decreased from high levels until the 1990s after which the trend has been increasing. In contrast, the MMB for WAG increased from a low in the 1990s until 2007/08 and then declined again. There has been a slight increase in MMB in WAG in the last several years. Recruitment for the EAG is variable with a generally increasing trend while recruitment for WAG is lower in recent years than during the 1980s. However, recruitment in 2015 for WAG appears to be relatively strong. Stock trends reflected the fishery standardized CPUE trends in both areas.

## Summary of major changes

The assessment model recommended by CPT is the same as the model used in the previous assessment. There were minor changes in the CPUE standardization and maturity breakpoint analysis that had negligible effects on assessment results.

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

The CPT recommends that this stock be managed as a Tier 3 stock in 2018/19. A single OFL and ABC is defined for AIGKC. However, separate models are available by area. The CPT recommends that stock status be determined by adding the estimates of current MMB and $B_{M S Y}$ by area. This stock status is then used to determine the ratio of $F_{\text {OFL }}$ to $F_{35 \%}$ by area, which is then used to calculate the OFLs by area which are then added together to calculate an OFL for the entire stock. The SSC has concurred with this approach. The stock is currently estimated to be above $\mathrm{B}_{\text {MSY }}$ in both areas therefore no adjustment is needed to the $F_{\text {OFL }}$ to determine the combined for both areas.

The CPT recommends that the $B_{M S Y \text { proxy }}$ for the Tier 3 harvest control rule be based on the average recruitment from 1987-2012, years for which recruitment is relatively precisely estimated.

Status and catch specifications (1000 t) of Aleutian Islands golden king crab.

| Year | MSST | Biomass <br> $(M M B)$ | TAC | Retained $^{\text {Catch }^{\mathbf{a}}}$ | Total <br> Catch $^{\mathbf{a}}$ | OFL | ABC |

| $2014 / 15$ | N/A | N/A | 2.853 | 2.771 | 2.967 | 5.69 | 4.26 |
| $2015 / 16$ | N/A | N/A | 2.853 | 2.729 | 2.964 | 5.69 | 4.26 |
| $2016 / 17$ | N/A | N/A | 2.515 | 2.593 | 2.829 | 5.69 | 4.26 |
| $2017 / 18$ | 6.044 | 14.205 | 2.515 | 2.585 | 2.942 | 6.048 | 4.536 |
| $2018 / 19$ |  | 17.952 |  |  |  | 5.514 | 4.136 |

a. Total retained catch plus estimated bycatch mortality of discarded bycatch during crab fisheries and groundfish fisheries.

Status and catch specifications (million lb) of Aleutian Islands golden king crab.

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch $^{\mathrm{a}}$ | OFL | ABC |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $2014 / 15$ | N/A | N/A | 6.290 | 6.11 | 6.54 | 12.53 | 9.40 |
| $2015 / 16$ | N/A | N/A | 6.290 | 6.016 | 6.54 | 12.53 | 9.40 |
| $2016 / 17$ | N/A | N/A | 5.545 | 5.716 | 6.24 | 12.53 | 9.40 |
| $2017 / 18$ | 13.325 | 31.315 | 5.545 | 5.699 | 6.49 | 13.33 | 10.00 |
| $2018 / 19$ |  | 39.577 |  |  |  | 12.16 | 9.12 |

a. Total retained catch plus estimated bycatch mortality of discarded bycatch during crab fisheries and groundfish fisheries.

The MMB is above MSST in 2017/18 therefore the stock is not overfished. Catch was below the OFL in 2017/18 therefore overfishing did not occur.

## Additional Plan Team recommendations

The CPT recommended additional assessment work in a number of areas. Additional development is needed for CPUE standardization, including consideration of year-area interactions, and continued development of the VAST spatial modeling approach. The chela measurement data should be reanalyzed to better estimate the maturity of AI golden king crab. Improvements are needed in the method used to project the OFL and ABC for the upcoming fishing year. Finally, additional work is needed to obtain an index using the cooperative pot survey data for use in the EAG assessment model.

## $9 \quad$ Pribilof District Golden King Crab

In accordance with the approved schedule, no assessment was conducted for Pribilof District golden king crab this year, however, a full stock assessment will be conducted in 2020. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018/19 specifications. Additional information listed below summarizes the 2017 assessment.

## Fishery information relative to OFL setting

The Pribilof District golden king crab fishery began in the 1981/82 season but is currently managed by calendar year. The directed fishery mainly occurs in Pribilof Canyon of the continental slope. Peak directed harvest was 0.856 million 1 b ( 388 t ) by 50 vessels during the 1983/84 season; fishery participation has since been sporadic and retained catches vary from 0 to 0.342 million lb ( 155 t ). A guideline harvest level (GHL) was first established in 1999 at 0.200 million $\mathrm{lb}(91 \mathrm{t})$ and the fishery has been managed with a GHL of 0.150 million $\mathrm{lb}(68 \mathrm{t})$ since 2000 . No directed fishery occurred during 2006-2009, but one vessel landed catch in 2010, two vessels landed catch in 2011, one vessel landed catch each year from 2012 to 2014, and two vessels landed catch in 2017. No vessels participated in the directed fishery during 2015 or 2016. Discarded (non-retained) catch has occurred in the directed golden king crab fishery, the eastern Bering Sea snow crab fishery, the Bering Sea grooved Tanner crab fishery, and in Bering Sea groundfish fisheries. Estimates of annual total fishery mortality during 2001-2017 due to crab fisheries range from 00.160 million $\mathrm{lb}(73 \mathrm{t})$. Estimates of annual fishery mortality during 1991/92-2017 due to groundfish fisheries range from $<0.001$ to 0.019 million lb ( 8.84 t ). Total fishery mortality in groundfish fisheries during the 2017 crab fishing year was 1.28 t .

## Data and assessment methodology

There is no assessment model for this stock. Fish ticket and observer data are available, size-frequency data from samples of landed crabs, and pot lifts sampled during the fishery, and from the groundfish fisheries. Much of the directed fishery data are confidential due to low participation levels. A random effects model using slope survey data was explored; however, the model fit was poor for mature and legal-size male, likely due to small number of data points and the high variance.

## Stock biomass and recruitment trends

There is no stock biomass data used in this Tier 5 assessment.
Tier determination/Plan Team discussion and resulting OFL and ABC determination
The CPT recommends this stock be managed under Tier 5 in 2018, 2019, and 2020. The CPT concurs with the author's recommended status quo OFL of 0.20 million lb and an ABC of 0.15 million lb . The ABC was derived by applying a $25 \%$ buffer of the $\mathrm{OFL}, \mathrm{ABC}=0.75 *$ OFL, the same buffer used for other Tier 5 stocks with similar levels of concern. The 2018-2020 OFL calculation is the same as recommended by the SSC for 2012-2017:
$\mathrm{OFL}_{2018-2020}=\left(1+\mathrm{R}_{2001-2010}\right) * \mathrm{RET}_{1993-1998}+\mathrm{BM}_{\mathrm{NC}, 1994-1998}+\mathrm{BM}_{\mathrm{GF}, 1992 / 93-1998 / 99}$ where,

- $\mathbf{R}_{2001-2010}$ is the average of the estimated annual ratio of lb of bycatch mortality to lb of retained in the directed fishery during 2001-2010.
- $\mathrm{RET}_{1993-1998}$ is the average annual retained catch in the directed crab fishery during 19931998.

## - $\mathrm{BM}_{\mathrm{NC}, 1994-1998}$ is the estimated average annual bycatch mortality in non-directed crab fisheries during 1994-1998. <br> - $\mathrm{BM}_{\mathrm{GF}, 1992 / 93-1998 / 99}$ is the estimated average annual bycatch mortality in groundfish fisheries during 1992/93-1998/99

## 10 Western Aleutian Islands red king crab

In accordance with the approved schedule, no assessment was conducted for Western Aleutian Islands king crab this year, however, a full stock assessment will be conducted in 2020 . Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018/19 specifications. Additional information listed below summarizes the 2017 assessment.

Fishery information relative to OFL and ABC setting
The domestic fishery has been prosecuted every season from 1960/61 to 1995/96. During the early years of the fishery through the late 1970 s, most or all of the retained catch was harvested in the area between $172^{\circ} \mathrm{W}$ longitude and $179^{\circ} 15^{\prime} \mathrm{W}$ longitude. Peak harvest occurred during the $1964 / 65$ season with a retained catch of 21.19 million lb . As the annual retained catch decreased into the mid-1970s and the early-1980s, the area west of $179^{\circ} 15^{\prime} \mathrm{W}$ longitude began to account for a larger portion of the retained catch. After 1995/96, the fishery was opened only occasionally. There was an exploratory fishery in 1998/99, three commissioner's permit fisheries in limited areas during 2000/01-2002/03 to allow for ADF\&G-Industry surveys, and two commercial fisheries with a GHL of 0.5 million lb in 2002/03 and 2003/04 in the Petrel Bank area. The fishery has been closed since 2003/04.

Retained catch from 1985/86 to 1994/95 averaged 0.94 million lb, but the retained catch during the 1995/96 season dropped to 0.04 million lb. Most of the catch since the 1990/91 season was harvested in the Petrel Bank area (between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude) and the last two commercial fishery seasons were opened only in the Petrel Bank area with 0.51 million lb in 2002/03 and 0.48 million lb in 2003/04. Non-retained catch of red king crabs occurs in both the directed red king crab fishery, the Aleutian Islands golden king crab fishery, and in groundfish fisheries. Estimated bycatch mortality in the crab fisheries during the 1995/96 to 2017/18 seasons averaged 0.002 million lb in crab fisheries and 0.015 million lb in groundfish fisheries. Estimated annual total fishing mortality from 1995/96 to 2017/18 averaged 0.072 million lb . The average retained catch during that period was 0.054 million lb . This fishery is rationalized under the Crab Rationalization Program only for the area west of $179^{\circ} \mathrm{W}$ longitude.

## Data and assessment methodology

The 1960/61 to 2007/08 time series of retained catch (number and pounds of crabs), effort (vessels, landings and pot lifts), average weight and average carapace length of landed crabs, and catch-per-unit effort (number of crabs per pot lift) are available. Bycatch from crab fisheries from 1995/96 to 2017/18 and from groundfish fisheries from 1993/94 to 2017/18 are available. There is no assessment model for this stock. The standardized surveys of the Petrel Bank area conducted by ADF\&G in 2006 and 2009 and the ADF\&G-Industry Petrel Bank surveys conducted in 2001 were too limited in geographic scope and too infrequent for reliable estimation of abundance for the entire western Aleutian Islands area.

## Stock biomass and recruitment trends

Estimates of stock biomass, recruitment trends, and current levels relative to virgin or historic levels are not available for this stock. The fishery has been closed since 2003/04 due to apparent poor recruitment. A 2009 survey conducted by ADF\&G in the Petrel Bank area encountered an ageing population of legal male crab occurring in a more limited area and at lower densities than were found in a 2006 survey and provided no expectations for recruitment. A test fishery conducted by a commercial vessel during October-December 2009 in the area west of Petrel Bank yielded only one legal male red king crab. A cooperative red king crab survey was performed by the Aleutian Islands King Crab Foundation and ADF\&G in the Petrel Bank area in November 2016 averaged less than one crab per pot lift suggesting that the stock is in poor condition.

## Tier determination/Plan Team discussion and resulting OFL and ABC determination

The CPT recommends that this stock be managed under Tier 5 for the 2017/18, 2018/19, and 2019/20 seasons. The CPT concurs with the assessment author's recommendation of an OFL based on the 1995/96-2007/08 average total catch following the recommendation of the SSC in June 2010 to set the time period for computing the OFL at 1995/96-2007/08. The CPT recommends an OFL for 2017/18 to 2019/20 of 0.123867 million lb.

The CPT continues to have concerns regarding the depleted condition of this stock. Groundfish bycatch in recent years has accounted for the majority of the total catch. The CPT recommends an ABC of 0.030967 million lb for 2017/18, 2018/19, and 2019/20 which is equivalent to a $75 \%$ buffer on OFL. The recommended ABC is less than that which was recommended by the SSC for 2012/13-2016/17 because (1) the industry has not expressed interest in a small test fishery, and (2) because the stock is severely depressed as indicated by the 2016 Petrel survey (CPT minutes for May 2017).

## Figures and Tables

## EBS crab stocks

Figure 1. Status of 6 Bering Sea crab stocks in relation to status determination criteria (BMSY, MSST, overfishing) for 2018. Status of PIBKC, PIRKC is based upon the 2017 assessment. Note that information is insufficient to assess Tier 5 stocks according to these criteria (WAIRKC, PIGKC).

Table 4. Crab Plan Team recommendations for September 2018. Note that recommendations for stocks 7, 8 represent those final values from the SSC in February and June 2018 while $4,5,9,10$ represent the most recent assessment in 2017. Hatched areas indicate parameters not applicable for that tier. Values are in thousand metric tons (kt).

Population dynamics
Likelihood components

1. Stock: Eastern Bering Sea snow crab, Chionoecetes opilio.
2. Catches: trends and current levels

Retained catches increased from relatively low levels in the early 1980s (e.g. retained catch of 11.85 kt during 1982) to historical highs in the early and mid-nineties (retained catch during 1991, 1992, and 1998 were $143.02,104.68$, and 88.09 kt , respectively). The stock was declared overfished in 1999 at which time retained catches dropped to levels similar to the early 1980s (e.g. retained catch during 2000 was 11.46 kt ). Retained catches have slowly increased since 1999 as the stock rebuilt, although retained catch during 2017 was low ( 8.6 kt ) as a result of low estimated mature biomass.

Discard mortality is the next largest source of mortality after retained catch and approximately tracks the retained catch. The highest estimated discard mortality occurred during 1992 at 17.06 kt which was $16 \%$ of the retained catch. The most recent estimated discard mortality was 1.93 kt which was $22 \%$ of the retained catch.

## 3. Stock Biomass:

Observed mature male biomass (MMB) at the time of the survey increased from an average of 234.14 kt in the early to mid-1980s to historical highs in the early and mid-nineties (observed MMB during 1990, 1991, and 1997 were $443.79,466.61$, and 326.75 kt , respectively). The stock was declared overfished in 1999 in response to the total mature biomass dropping below the minimum stock size threshold. MMB in that year decreased to 95.85 kt . Observed MMB slowly increased after 1999, and the stock was declared rebuilt in 2011 when estimated MMB at mating was above $\mathrm{B}_{35 \%}$. However, since 2011, the stock has declined again and the observed MMB at the time of survey dropped to an all time low in 2017 of 83.96 kt . This year's MMB (2018) marks the highest observed at the time of the survey since 1998.

## 4. Recruitment

Estimated recruitment shifted from a period of high recruitment to a period of low recruitment in the mid 1990s (late 1980s when lagged to fertilization). Recently, a large year class recruited to the survey gear, appears to have persisted to the present, and is beginning to be seen in the exploitable biomass.
5. Management

Table 1: Historical status and catch specifications for snow crab (1,000t).

| Year | MSST | Biomass <br> $(M M B)$ | TAC | Retained <br> catch | Total <br> catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 2015$ | 73.2 | 129.3 | 30.8 | 30.8 | 34.3 | 69 | 62.1 |
| $2015 / 2016$ | 75.8 | 91.6 | 18.4 | 18.4 | 21.4 | 83.1 | 62.3 |
| $2016 / 2017$ | 69.7 | 96.1 | 9.7 | 9.7 | 11 | 23.7 | 21.3 |
| $2017 / 2018$ | 71.4 | 99.6 | 8.6 | 8.6 | 10.5 | 28.4 | 22.7 |
| $2018 / 2019$ |  | 123.1 |  |  |  | 29.7 | 23.8 |

Table 2: Historical status and catch specifications for snow crab (millions of lbs).

| Year | MSST | Biomass <br> $($ MMB $)$ | TAC | Retained <br> catch | Total <br> catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 2015$ | 161.38 | 285.06 | 67.9 | 67.9 | 75.62 | 152.12 | 136.91 |
| $2015 / 2016$ | 167.11 | 201.94 | 40.57 | 40.57 | 47.18 | 183.2 | 137.35 |
| $2016 / 2017$ | 153.66 | 211.86 | 21.38 | 21.38 | 24.25 | 52.25 | 46.96 |
| $2017 / 2018$ | 157.41 | 219.58 | 18.96 | 18.96 | 23.15 | 62.61 | 50.04 |
| $2018 / 2019$ |  | 271.39 |  |  |  | 65.48 | 52.47 |

6. Basis for the OFL

The OFL for 2018 from the chosen model (Sep devs) was 29.74 kt fishing at $\mathrm{F}_{\text {OFL }}=1.04$ ( $85 \%$ of the calculated $\mathrm{F}_{35 \%}, 1.22$ ). The calculated OFL was a $5 \%$ change from the 2017 OFL of 28.4 kt . The projected ratio of MMB at the time of mating in 2019 to $\mathrm{B}_{35 \%}$ is 0.86 .

Table 3: Metrics used in designation of status and OFL (1,000 t). 'Years' indicate the year range over which recruitment is averaged for use in calculation of B35. ' M ' is the natural mortality for immature crab, mature male crab, and mature female crab, respectively.

| Year | Tier | BMSY | MMB | Status | FOFL | Years | M |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2017 / 2018$ | 3 | 142.8 | 99.6 | 0.7 | 1.04 | $1982-2017$ | $0.27,0.26,0.36$ |

Table 4: Metrics used in designation of status and OFL (millions of lb.). 'Years' indicate the year range over which recruitment is averaged for use in calculation of B35. 'Status' is the ratio between MMB and BMSY. ' M ' is the natural mortality for immature crab, mature male crab, and mature female crab, respectively.

| Year | Tier | BMSY | MMB | Status | FOFL | Years | M |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2017 / 2018$ | 3 | 314.8 | 219.6 | 0.7 | 1.04 | $1982-2017$ | $0.27,0.26,0.36$ |

7. Probability Density Function of the OFL

The probability density function of the OFL was characterized for all models by using maximum likelihood estimates of the OFL and associated standard errors. PDFs of the OFL for selected models were characterized using a Markov Chain Monte Carlo algorithm to sample from its posterior distribution. Reported OFLs are maximum likelihood estimates because of pathologies in the MCMC output.
8. Basis for ABC

The ABC for the chosen model was 23.79 kt , calculated by subtracting a $20 \%$ buffer from the OFL as recommended by the SSC.

## A. Summary of Major Changes

1. Management: None
2. Input data:

Data added to the assessment included: 2018 Bering Sea survey biomass and length frequency data, 2017 directed fishery retained and discard catch and length frequencies for retained and discard catch, and groundfish discard length frequency and discard from 2017. Growth data were updated with 70 observations of pre- and post-molt lengths ( 45 for females; 25 for males).
3. Assessment methodology:

The recommended OFL was calculated using Bayesian methodologies in 2016 and 2017, which was a departure from the previous projection framework (but provided similar management advice). Both a maximum likelihood approach (including 'jittering') and a Bayesian treatment of the data were completed for selected models this year. Management quantities from the author chosen model are reported as the maximum likelihood estimates because of convergence issues with MCMC.
4. Assessment results

The updated estimate of MMB (February 15, 2017) was 85.84 which placed the stock at $60 \%$ of $\mathrm{B}_{35 \%}$. Projected MMB on February 15, 2018 from this assessment's chosen model was 123.07 kt after fishing at the OFL, which will place the stock at $86 \%$ of $\mathrm{B}_{35 \%}$. Fits to all data sources were acceptable for the chosen model and most estimated population processes were credible (see discussion below).

## B. CPT May 2018 comments, SSC comments, and author response:

## CPT and SSC comments

The CPT made three recommendations for scenarios to be presented in September based on analyses presented during the May 2018 CPT meeting:

- 2017 accepted model-Estimate M for females, males, and immature crab.
- Fix female M-The same model as above, but fix natural mortality for mature females at 0.23 , to match the 2016 accepted model.
- Fit the model to total and retained size composition data, rather than the total and discarded size comps.

The CPT also recommended resolving problems with any parameters hitting bounds. The SSC agreed with these suggestions and proposed additional runs to explore the impact of priors on natural mortality. The SSC suggested exploring the potential that catchability for the BSFRF data was not 1 by locating information (e.g. underwater video of surveys) to inform this assumption. The SSC also noted potential issues with the mixing of several parameters when implementing an MCMC algorithm and suggested that the model 'may now be getting too complicated'. The SSC supported an increase of the buffer for the ABC from $10 \%$ to $20 \%$.

The author presents 7 runs based on these recommendations:

- "2017 Accepted" - Last year's accepted model fit to last year's data.
- "New Data" - Last year's accepted model fit to this year's data.
- "Fix fem M" - Last year's accepted model fit to this year's data, but turning off estimation of mature female natural mortality to more closely match the 2016 accepted model.
- "Loose prior M" - Estimate mature female natural mortality (and mature male and immature female and male), but use a less informative prior.
- "Looser prior M" - Estimate mature female natural mortality (and mature male and immature female and male), but use an even less informative prior.
- "Sep devs" - Estimate recruitment deviations for males and females instead of using a common recruitment between sexes. This is an addition of the author's, given the runs in the residuals of the fits to the survey mature biomass and observed retrospective patterns. Female mature biomass is underestimated in recent years, whereas male biomass is overestimated. Potential rationale for fitting different recruitment deviations by sex include different growth rates between sexes (resulting in different ages of crab by sex in the first length bins) and different observed spatial distribution of immature females and males.
- "Sep devs + loose prior M" - Combine "Sep devs" and "Loose prior M"
- "Sep devs + looser prior M" - Combine "Sep devs" and "Looser prior M"
- "Sep devs + loose + growth" - Combine "Sep devs" and "Loose prior M", but replace the the 'kinked' growth curves for males and females with linear growth.

## Authors response

Most of the SSC and CPT's suggestions are addressed in this assessment and changes within were undertaken in a step-wise fashion. Model scenarios include all CPT recommended models.
'Jittering' was performed for all models, but did not perform as well last year's implementation in identifying a mode of likelihood to which many runs of the same model configuration converged. Jittering the models with all new data for 2018 produced less stable estimates of management quantities than in 2017, so two additional model runs were performed in which the newest catch and survey data and new growth data were added separately to explore their relative impact on the stability of the model. Bimodality was a problem in some models. Given what appears to be instability in convergence in the maximum likelihood estimation, Bayesian posteriors of management quantities were also calculated for selected models. However, the Bayesian methods also had difficulties converging. Retrospective analyses for selected models were also performed.

Tentatively, "Sep devs" is the author preferred model based on fit to the data, the number of assumptions placed on the data, and the magnitude of retrospective patterns (see discussion below). However, the author looks forward to discussion and guidance from the CPT on this issue.
It should be noted that fitting the model to total and retained size composition is already done in previous assessments, but the data input as discards and retained composition data, then summed in the code. Also, the author has been in contact with the BSFRF and hopes to procure video to explore the assumption of $q=$ 1 for the BSFRF gear in the future.

## C. Introduction

## Distribution

Snow crab (Chionoecetes opilio) are distributed on the continental shelf of the Bering Sea, Chukchi Sea, and in the western Atlantic Ocean as far south as Maine. In the Bering Sea, snow crab are distributed widely over the shelf and are common at depths less than $\sim 200$ meters (Figure $1 \&$ Figure 2). Smaller crabs tend to occupy more inshore northern regions (Figure 3) and mature crabs occupy deeper areas to the south of the juveniles (Figure 4 \& Figure 5; Zheng et al. 2001). The eastern Bering Sea population within U.S. waters is managed as a single stock; however, the distribution of the population may extend into Russian waters to an unknown degree.

## Life history characteristics

Studies relevant to key population and fishery processes are discussed below to provide background for the model description in appendix A.

## Natural Mortality

Natural mortality for snow crab in the Bering Sea is poorly known, due to relatively few targeted studies. In one of these studies, Nevissi, et al. (1995) used radiometric techniques to estimate shell age from last molt. The total sample size was 21 male crabs (a combination of Tanner and snow crab) from a collection of 105 male crabs from various hauls in the 1992 and 1993 NMFS Bering Sea survey. Representative samples for the 5 shell condition categories were collected that made up the 105 samples. The oldest looking crab within shell conditions 4 and 5 were selected from the total sample of SC 4 and SC 5 crabs to radiometrically age (Orensanz, Univ. of Washington, pers comm.). Shell condition 5 crab (SC5 = very, very old shell) had a maximum age of 6.85 years (s.d. $0.58,95 \%$ CI approximately 5.69 to 8.01 years). The average age of 6 crabs with SC4 (very old shell) and SC5, was 4.95 years (range: 2.70 to 6.85 years). Given the small sample size, this maximum age may not represent the $1.5 \%$ percentile of the population that is approximately equivalent to Hoenig's method (1983). Maximum life span defined for a virgin stock is reasonably expected to be longer than these observed maximum ages from exploited populations, particularly because fishing mortality was high before and during the time period during which this study was performed. Radiometric ages estimated by Nevissi, et al. (1995) may also be underestimated by several years, due to the continued exchange of material in crab shells even after shells have hardened (Craig Kastelle, pers. comm., Alaska Fisheries Science Center, Seattle, WA).

Tag recovery evidence from eastern Canada revealed observed maximum ages in exploited populations of 17-19 years (Nevissi, et al. 1995, Sainte-Marie 2002). A maximum time at large of 11 years for tag returns of terminally molted mature male snow crab in the North Atlantic has been recorded since tagging started about 1993 (Fonseca, et al. 2008). Fonseca, et al. (2008) estimated a maximum age of 7.8 years post terminal molt using data on dactal wear. Murphy et al. (2018) estimated time-varying natural mortality for eastern Bering Sea snow crab with a mean of 0.49 for females and 0.36 for males (based on the NMFS survey data and state space models).

The mean for the prior for natural mortality used in this assessment is based on the assumption (informed by the studies above) that longevity would be at least 20 years in a virgin population of snow crab. Under negative exponential depletion, the 99 th percentile corresponding to age 20 of an unexploited population corresponds to a natural mortality rate of 0.23 . Using Hoenig's (1983) method a natural mortality equal to 0.23 corresponds to a maximum age of 18 years. Given this background, the mean of the prior on natural mortality for immature males and females, mature males, and mature females was set to $0.23 \mathrm{yr}^{-1}$.

In one model "Fix fem M", mature female was not estimated. In all others, natural mortality was estimated with varying standard errors for the prior distribution around the mean. Natural mortality was estimated in

2017 with a standard error equal to 0.054 . Models down-weighting the prior on natural mortality (e.g. "Loose prior M", "Looser prior M", and their derivatives), used standard errors of 0.154 and 2.154, respectively, to reduce the impact of the prior in model fitting (Figure 6). The standard error of 0.054 was estimated using the $95 \%$ CI of +-1.7 years on maximum age estimates from dactal wear and tag return analysis in Fonseca, et al. (2008).

## Weight at length

Weight at length is calculated by a power function, the parameters for which were recalculated by the Kodiak lab in August 2016 and resulted in very small changes in weight at length for males, but rather large changes for females. New weight at length parameters were applied to all years of data, rather than just the most recent observations and were used starting in 2016 for calculation of the OFL. To provide context for the change, a juvenile female crab of carapace width 52.5 mm was previously estimated to weigh 65 g and is now 48 g ; a mature female crab of carapace width 57.5 mm was estimated to previously weigh 102 g and is now 67.7 g ; and a male of carapace width 92.5 mm was previously estimated to weigh 450 g and now weighs 451 g .

## Maturity

Maturity of females collected during the NMFS summer survey was determined by the shape of the abdomen, by the presence of brooded eggs, or egg remnants. Morphometric maturity for males was determined by chela height measurements, which were available starting from the 1989 survey (Otto 1998). Mature male biomass referenced throughout this document refers to a morphometrically mature male. A maturity curve for males was estimated using the average fraction mature based on chela height data and applied to all years of survey data to estimate mature survey numbers. The separation of mature and immature males by chela height may not be adequately refined given the current measurement to the nearest millimeter. Chela height measured to the nearest tenth of a millimeter (by Canadian researchers on North Atlantic snow crab) shows a clear break in chela height at small and large widths and shows fewer mature animals at small widths than the Bering Sea data measured to the nearest millimeter. Measurements taken in 2004-2005 on Bering Sea snow crab chela to the nearest tenth of a millimeter show a similar break in chela height to the Canadian data (Rugolo et al. 2005). The probability of maturing (which is different from the fraction mature at length) is estimated within the model for both sexes as a freely estimated (but smoothed) function of length.

## Molting probability

Bering Sea male snow crab appear to have a terminal molt to maturity based on hormone level data and findings from molt stage analysis via setagenesis (Tamone et al. 2005). The models presented here assume a terminal molt for both males and females, which is supported by research on populations in the Bering Sea and the Atlantic Ocean (e.g., Dawe, et al. 1991).

Male snow crabs that do not molt (old shell) may be important in reproduction. Paul et al. (1995) found that old shell mature male Tanner crab out-competed new shell crab of the same size in breeding in a laboratory study. Recently molted males did not breed even with no competition and may not breed until after $\sim 100$ days from molting (Paul et al. 1995). Sainte-Marie et al. (2002) stated that only old shell males take part in mating for North Atlantic snow crab. If molting precludes males from breeding for a three month period, then males that are new shell at the time of the survey (June to July), would have molted during the preceding spring (March to April), and would not have participated in mating. The fishery targets new shell males, resulting in those animals that molted to maturity and to a size acceptable to the fishery of being removed from the population before the chance to mate. However, new shell males will be a mixture of crab less than 1 year from terminal molt and $1+$ years from terminal molt due to the inaccuracy of shell condition as a measure of shell age. Crabs in their first few years of life may molt more than once per year, however, the smallest crabs included in the model are approximately 4 years old and would be expected to molt annually. Further research on the relationship between shell condition and time from last molt is needed.

## Mating ratio and reproductive success

Bering Sea snow crabs are managed using mature male biomass (MMB) as a proxy for reproductive potential. MMB is used as the currency for management because the fishery only retains large male crabs. Male snow crabs are sperm conservers, using less than $4 \%$ of their sperm at each mating and females also will mate with more than one male. The amount of stored sperm and clutch fullness varies with sex ratio (Sainte-Marie 2002). If mating with only one male is inadequate to fertilize a full clutch, then females will need to mate with more than one male, necessitating a sex ratio closer to $1: 1$ in the mature population, than if one male is assumed to be able to adequately fertilize multiple females. Although mature male biomass is currently the currency of management, female biomass may also be an important indicator of reproductive potential of the stock.

Quantifying the reproductive potential of the female population from survey data can be less than straightforward. For example, full clutches of unfertilized eggs may be extruded and appear normal to visual examination, and may be retained for several weeks or months by snow crab. Resorption of eggs may occur if not all eggs are extruded resulting in less than a full clutch. Female snow crabs at the time of the survey may have a full clutch of eggs that are unfertilized, resulting in overestimation of reproductive potential. Barren females are a more obvious indication of low reproductive potential and increased in the early 1990s then decreased in the mid- 1990s then increased again in the late 1990s. The highest levels of barren females coincides with the peaks in catch and exploitation rates that occurred in 1992 and 1993 fishery seasons and the 1998 and 1999 fishery seasons. While the biomass of mature females was high in the early 1990s, it is possible the production may have been impacted by the spatial distribution of the catch and the resulting sex ratio in areas of highest reproductive potential. Biennial spawning is another confounding factor in determining the reproductive potential of snow crab. Laboratory analysis showed that female snow crab collected in waters colder than 1.5 degrees C from the Bering Sea spawn only every two years.
Further complicating the process of quantifying reproductive capacity, clutch fullness and fraction of unmated females may not account for the fraction of females that may have unfertilized eggs, since these cannot be detected by the naked eye at the time of the survey. The fraction of barren females observed in the survey may not be an accurate measure of fertilization success because females may retain unfertilized eggs for months after extrusion. To examine this hypothesis, RACE personnel sampled mature females from the Bering Sea in winter and held them in tanks until their eggs hatched in March of the same year (Rugolo et al. 2005). All females then extruded a new clutch of eggs in the absence of males. All eggs were retained until the crabs were euthanized near the end of August. Approximately $20 \%$ of the females had full clutches of unfertilized eggs. The unfertilized eggs could not be distinguished from fertilized eggs by visual inspection at the time they were euthanized. Indices of fertilized females based on the visual inspection method of assessing clutch fullness and percent unmated females may overestimate fertilized females and may not be an accurate index of reproductive success.

## Growth

Historically, little information was available on growth for Bering Sea snow crab. However, this year's addition of 70 pre- and post-molt lengths brings the total to 110 data points derived from 6 studies used to estimate grow increments for females and males (Table 6). These studies include:

1. Transit study (Rugolo unpublished data, 2003); 14 crab
2. Cooperative seasonality study (Rugolo); 6 crab
3. Dutch harbor holding study; 9 crab
4. NMFS Kodiak holding study held less than 30 days; 6 crab
5. NMFS Kodiak holding study 2016; 5 crab
6. NMFS Kodiak holding study 2017; 70 crab.

Data from the NMFS Kodiak study 2017 are new for this year's assessment. In the "Transit study", preand post-molt measurements of 14 male crabs that molted soon after being captured were collected. The crabs were measured when shells were still soft because all died after molting, so measurements may be
underestimates of post-molt width (Rugolo, pers. com.). The holding studies include only data for crab held less than 30 days because growth of crabs held until the next spring's molting was much lower. Females molting to maturity were excluded from all data sets, since the molt increment is usually smaller. Crab missing more than two limbs were excluded due to other studies showing lower growth. Crab from Rugolo's seasonal study were excluded that were measured less than 3 days after molting due to difficulty in measuring soft crab accurately. In general, growth of snow crab in the Bering Sea appears to be greater than growth of some North Atlantic snow crab stocks (Sainte-Marie 1995).

## Management history

## ADFG harvest strategy

Before the year 2000, the Guideline Harvest Level (GHL) for retained crab only was a harvest rate $58 \%$ of the number of male crab over 101 mm CW estimated from the survey. The minimum legal size limit for snow crab is 78 mm , however, the snow crab market generally only accepts crab greater than 101 mm . In 2000, due to the decline in abundance and the declaration of the stock as overfished, the harvest rate for calculation of the GHL was reduced to $20 \%$ of male crab over 101 mm . After 2000, a rebuilding strategy was developed based on simulations by Zheng (2002) using survey biomass estimates. The realized retained catch typically exceeded the GHL historically, resulting in exploitation rates for the retained catch on males $>101 \mathrm{~mm}$ ranging from about $10 \%$ to $80 \%$. The estimated exploitation rate for total catch divided by mature male biomass ranged from $6 \%$ to $54 \%$ for the chosen model in this assessment (Figure 7).

The ADFG harvest strategy since 2000 sets harvest rate based on estimated mature biomass. The harvest rate scales with the status of the population relative to $\mathrm{B}_{M S Y}$, which is calculated as the average total mature biomass at the time of the survey from 1983 to 1997 and MSST is one half $\mathrm{B}_{M S Y}$. The harvest rate begins at 0.10 when total mature biomass exceeds $50 \%$ MSST ( 230 million lbs) and increases linearly to 0.225 when biomass is equal to or greater than $\mathrm{B}_{M S Y}$ (Zheng et al. 2002).

$$
u= \begin{cases}\text { Bycatch } & \text { if } \frac{T M B}{T M B_{M S Y}} \leq 0.25  \tag{1}\\ \frac{0.225\left(\frac{T M B}{T M B_{M S Y}}-\alpha\right)}{1-\alpha} & \text { if } 0.25<\frac{T M B}{T M B_{M S Y}}<1 \\ 0.225 & \text { ifTMB>TMB } B_{M S Y}\end{cases}
$$

The maximum retained catch is set as the product of the exploitation rate, $u$, calculated from the above control rule and survey mature male biomass. If the retained catch in numbers is greater than $58 \%$ of the estimated number of new shell crabs greater than 101 mm plus $25 \%$ of the old shell crab greater than 101 mm , the catch is capped at $58 \%$.

## History of BMSY

Prior to adoption of Amendment 24, $\mathrm{B}_{M S Y}$ was defined as the average total mature biomass (males and females) estimated from the survey for the years 1983 to 1997 ( 921.6 million lbs; NPFMC 1998) and MSST was defined as $50 \%$ of $\mathrm{B}_{M S Y}$. Definitions of biological reference points based on the biomass over a range of years make a host of assumptions that may or may not be fulfilled. Currently, the biological reference point for biomass is calculated using a spawning biomass per recruit proxy, $\mathrm{B}_{35 \%}$ (Clark, 1993). $\mathrm{B}_{35 \%}$ is the biomass at which spawning biomass per recruit is $35 \%$ of unfished levels and has been shown to provide close to maximum sustainable yield for a range of steepnesses (Clark, 1993). Consequently, it is an often used target when a stock recruit relationship is unknown or unreliable.

## Fishery history

Snow crab were harvested in the Bering Sea by the Japanese from the 1960s until 1980 when the Magnuson Act prohibited foreign fishing. After the closure to foreign fleets, retained catches increased from relatively low levels in the early 1980 s (e.g. retained catch of 11.85 kt during 1982) to historical highs in the early and mid-nineties (retained catch during 1991, 1992, and 1998 were $143.02,104.68$, and 88.09 kt , respectively). The stock was declared overfished in 1999 at which time retained catches dropped to levels similar to the early 1980s (e.g. retained catch during 2000 was 11.46 kt ). Retained catches have slowly increased since 1999 as the stock rebuilt, although retained catch during 2017 was low ( 8.6 kt ).

Discard mortality is the next largest source of mortality after retained catch and approximately tracks the retained catch. The highest estimated discard mortality occurred during 1992 at 17.06 kt which was $16 \%$ of the retained catch. The most recent estimated mortality was 1.93 kt which was $22 \%$ of the retained catch.

Discard from the directed pot fishery has been estimated from observer data since 1992 and ranged from $11 \%$ to $64 \%$ (average $33 \%$ ) of the retained catch of male crab biomass (Table 7). Female discard catch has been very low compared to male discard catch and has not been a significant source of mortality. Discard of snow crab in groundfish fisheries has been highest in the yellowfin sole trawl fishery, and decreases down through the flathead sole trawl fishery, Pacific cod bottom trawl fishery, rock sole trawl fishery, and the Pacific cod hook-and-line and pot fisheries, respectively (Figure 8). Bycatch in fisheries other than the groundfish trawl fishery has historically been relatively low, but in 2015 bycatch from sources other than the groundfish trawl fishery reached almost $\sim 25 \%$ of the reported bycatch. Size frequency data and catch per pot have been collected by observers on snow crab fishery vessels since 1992. Observer coverage has been $10 \%$ on catcher vessels larger than 125 ft (since 2001), and $100 \%$ coverage on catcher processors (since 1992).

Several modifications to pot gear have been introduced to reduce bycatch mortality. In the 1978/79 season, escape panels were introduced to pots used in the snow crab fishery to prevent ghost fishing. Escape panels consisted of an opening with one-half the perimeter of the tunnel eye laced with untreated cotton twine. The size of the cotton laced panel was increased in 1991 to at least 18 inches in length. No escape mechanisms for undersized crab were required until the 1997 season when at least one-third of one vertical surface of pots had to contain not less than 5 inches stretched mesh webbing or have no less than four circular rings of no less than $33 / 4$ inches inside diameter. In the 2001 season the escapement for undersized crab was increased to at least eight escape rings of no less than 4 inches placed within one mesh measurement from the bottom of the pot, with four escape rings on each side of the two sides of a four-sided pot, or one-half of one side of the pot must have a side panel composed of not less than $51 / 4$ inch stretched mesh webbing.

## D. Data

New time series of survey indices and size compositions were calculated from data downloaded from the AKFIN database. Bycatch data (biomass and size composition) were updated for the most recent year from the AKFIN database. Retained, total, and discarded catch (in numbers and biomass) and size composition data for each of these data sources were updated for the most recent year based on files provided by the State of Alaska.

## Catch data

Catch data and size composition of retained crab from the directed snow crab pot fishery from survey year 1978 to the 2017 were used in this analysis (Table 7). Size composition data on the total catch (retained plus discarded) in the directed crab fishery were available from survey year 1992 to 2017. Total discarded catch was estimated from observer data from 1992 to 2017 (Table 1). The discarded male catch was estimated for survey year 1978 to 1991 in the model using the estimated fishery selectivities based on the observer data for the period of survey year 1992 to 2017. The discard catch estimate was multiplied by the assumed mortality of discards from the pot fishery. The assumed mortality of discarded crab was $30 \%$ for all model
scenarios. This estimate differs from the currently used strategy (since 2001) to the present by ADFG to set the TAC, which assumes a discard mortality of $25 \%$ (Zheng, et al. 2002). The discards prior to 1992 may be underestimated due to the lack of escape mechanisms for undersized crab in the pots before 1997. See Table 5 for a summary of catch data.

Table 5: Data included in the assessment. Dates indicate survey year.

| Data component | Years |
| :--- | :---: |
| Retained male crab pot fishery size frequency by shell condition | $1982-2017$ |
| Discarded Males and female crab pot fishery size frequencey | $1992-2017$ |
| Trawl fishery bycatch size frequencies by sex | $1991-2017$ |
| Survey size frequencies by sex and shell condition | $1982-2018$ |
| Retained catch estimates | $1982-2017$ |
| Discard catch estimates from crab pot fishery | $1992-2017$ |
| Trawl bycatch estimates | $1993-2017$ |
| Total survey biomass estimates and coefficients of variation | $1982-2018$ |
| 2009 study area biomass estimates, CVs, and size frequencey for BSFRF and NMFS | 2009 |
| tows | 2010 |
| 2010 study area biomass estimates, CVs, and size frequencey for BSFRF and NMFS | 20 |

## Survey biomass and size composition data

Abundance was estimated from the annual eastern Bering Sea (EBS) bottom trawl survey conducted by NMFS (see Rugolo et al. 2003 for design and methods). In 1982 the survey net was changed resulting in a potential change in catchability and additional survey stations were added in 1989. Consequently, survey selectivity has been historically modeled in three 'eras' in the assessment (1978-1981, 1982-1988, 1989-present). Currently only data from 1982 onward are used in the assessment-a change adopted in the 2017 assessment (Figure 9). All survey data in this assessment used measured net widths instead of the fixed 50 ft net width based on Chilton et al.'s (2009) survey estimates. Carapace width and shell conditions were measured and reported for snow crab caught in the survey.

Mature biomass for males and females at the time of the survey were the primary indices of population size fit to in this assessment. Total survey numbers (Figure $10 \&$ Figure 11) were input to the model via the .DAT file, after which MMB and FMB at the time of the survey were calculated based on the size composition data, which were delineated by shell condition, maturity state, and sex. Distinguishing between mature and immature crab for the size composition was accomplished by demarcating any female that had eggs reported in the survey as 'mature'. Mature male size composition data were calculated by multiplying the total numbers at length for new shell male crab by a vector of observed proportion of mature males at length. The observed proportion of mature males at length was calculated by chelae height and therefore refers only to 'morphometrically' mature males. All old shell crab of both sexes were assumed to be mature. New shell crab were demarcated as any crab with shell condition index $<=2$. The biomass of new and old shell mature individuals was calculated by multiplying the vector of numbers at length by weight at length. These vectors were then summed by sex to provide the index to which the model was fit (Table 8). The size composition data were also fit within the assessment.

## Spatial distribution of survey abundance and catch

Spatial gradients exist in the survey data by maturity and size for both sexes. For example, larger males have been more prevalent on the south west portion of the shelf (Figure 4) while smaller males have been more prevalent on the north west portion of the shelf (Figure 1). Females have exhibited a similar pattern
(compare Figure 2 to Figure 5). In addition to changing spatially over the size and shelf, distributions of crab by size and maturity have also changed temporally. The centroids of abundance in the summer survey have moved over time (Figure $12 \&$ Figure 13). Centroids of mature female abundance early in the history of the survey were the farther south, but moved north during the 1990s. Since the late 1990s and early 2000s, the centroids moved south again, but not to the extent seen in the early 1980s. This phenomenon was mirrored in centroids of abundance for large males (Figure 13).

Centroids of the catch were generally south of 58.5 N , even when ice cover did not restrict the fishery moving farther north. This is possibly due to proximity to port and practical constraints of meeting delivery schedules. The majority of catch was taken west and north of the Pribilof Islands, but this rule has had exceptions.

The distribution of large males during the summer survey and the fishery catch are different. The origin of this difference is unknown. It is possible that crab move between the fishery and the survey, but it is also possible that fishers did not target all portions of the distribution of large male crab equally. The underlying explanation of this phenomenon could hold implications for relative exploitation rates spatially and it has been suggested that high exploitation rates in the southern portion of the snow crab range may have resulted in a northward shift in snow crab distribution (Orensanz, 2004). Snow crab larvae likely drift north and east after hatching in spring. Snow crab appear to move south and west as they age (Parada et al., 2010), however, little tagging data exists to fully characterize the ontogenetic or annual migration patterns of this stock (Murphy et al. 2010).

## Experimental study of survey selectivity

The Bering Sea Fisheries Research Foundation (BSFRF) conducted a survey of 108 tows in 27 survey stations (hereafter referred to as the 'study area') in the Bering Sea in summer 2009 (Figure 14). The BSFRF performed a similar study during 2010 in which the study area covered a larger portion of the distribution of snow crab than the 2009 study area. The mature biomass and size composition data gleaned from each of these experiments (and their complimentary NMFS survey observations; Figure $15 \&$ Figure 16) are incorporated into the model by fitting them as an extra survey that is linked to the NMFS survey through a shared selectivity (see appendix A for a description of the way in which the surveys are related in the assessment model). Abundances estimated by the industry surveys were generally higher than the NMFS estimates, which provides evidence that the catchability of the NMFS survey gear is less than 1. Larger females are an exceptions to this observation, but this difference may be due to different towing locations for the two nets within the study area, or to variable catchability of females due to aggregation behavior.

## E. Analytic approach

## History of modeling approaches for the stock

Historically, survey estimates of large males ( $>101 \mathrm{~mm}$ ) were the basis for calculating the Guideline Harvest Level (GHL) for retained catch. A harvest strategy was developed using a simulation model that pre-dated the current stock assessment model (Zheng et al. 2002). This model has been used to set the GHL (renamed total allowable catch, 'TAC' since 2009) by Alaska Department of Fish and Game (ADFG) since the 2000/2001 fishery. Currently, NMFS uses an integrated size-structured assessment to calculate the overfishing level (OFL), which constrains the ADFG harvest strategy.

## Model description

The integrated size-structured model used by NMFS (and presented here) was developed following Fournier and Archibald's (1982) methods, with many similarities to Methot (1990). The model was implemented using automatic differentiation software developed as a set of libraries under $\mathrm{C}++$ (ADModel Builder). ADModel

Builder can estimate a large number of parameters in a non-linear model using automatic differentiation software extended from Greiwank and Corliss (1991) and developed into C++ class libraries.

The snow crab population dynamics model tracked the number of crab of sex $s$, shell condition $v$, maturity state $m$, during year $y$ at length $l, \mathrm{~N}_{s, v, m, y, l}$. A terminal molt was modeled in which crab move from an immature to a mature state, after which no further molting occurred. The mid-points of the size bins tracked in the model spanned from 27.5 to 132.5 mm carapace width, with 5 mm size classes. For the base assessment ( 2017 model_new data), 323 parameters were estimated. Parameters estimated within the assessment included those associated with the population processes recruitment, growth, natural mortality (historically subject to a fairly informative prior), fishing mortality, selectivity (fishery and survey), catchability, and maturity (also sometimes subject to a prior; see Table $9 \&$ Table 10). Weight at length, discard mortality, bycatch mortality, and parameters associated with the variance in growth and proportion of recruitment allocated to size bin were estimated outside of the model or specified. See appendix A for a complete description of the population dynamics.
In the past a 'jittering' approach was explored in order to find the parameter vector that produced the smallest negative log likelihood (Turnock, 2016). Jittering was implemented here by running each model to produce a .PAR file, then creating 70 replicates of a .PIN file using that .PAR file. Each .PIN file consisted of the values in the .PAR file multiplied by a random normal error term with a mean of 1 and a standard deviation of 0.1. Only values for parameters that are estimated were 'jittered'. Each of the .PIN files were used as starting values to run the model and the output was stored and compared among model scenarios. The model that returned the lowest negative log likelihood within a given model scenario was then used for comparison here.

Samples were also drawn from the posterior distributions of estimated parameters and derived quantities used in management (e.g. MMB and OFL) via MCMC for select models. This involved conducting 10,000,000 cycles of the MCMC algorithm, implementing a $5 \%$ burn-in period, and saving every 2000th draw. Chains were then thinned until diagnostic statistics (e.g. Geweke statistics and autocorrelation) demonstrated a lack of evidence of non-convergence (if possible).
Retrospective analyses were performed in which the terminal year of data was removed sequentially and a given model was refit to each subset of the data. Then estimated management quantities (like MMB) were compared between the most recent model and successive 'peels' of the data to identify retrospective patterns. A retrospective pattern is a consistent directional change in assessment estimates of management quantities (e.g. MMB) in a given year when additional years of data are added to an assessment.

## Model selection and evaluation

Models were evaluated based on their fit to the data (Table 11), the credibility of the estimated population processes, stability of the model (Figure 17, Figure 18, Figure 19), and the strength of the influence of the assumptions of the model on the outcomes of the assessment. Maximum likelihood estimates of parameters can be seen in Table 10 and their posterior distributions can be seen for selected models in Figure 20, Figure 21, Figure 22, and Figure 23 (these posterior distributions are for illustrative purposes only in this assessment given poor convergence).

## Results

Several of the models exhibited unstable behavior when jittered (Figure 18). The new survey and catch data appear to be a bigger driver of the instability than the additional growth data (Figure 17). Models appeared to 'converge' (i.e. small gradients) over a wide range of likelihood values and derived management quantities exhibited bimodality to some degree for several models. This bimodality can still be linked to the change point growth model (Figure 24).

In addition to jittering, MCMC was performed for selected models ("2017 model_new data" \& "Loose prior M"). Both models appeared to converge acceptably on first glance (Figure 19). However, MCMC for "2017
model_new data" failed-ten millions draws ( $\sim 65$ hours) produced posteriors with very little variability (in spite of what appeared to be plausible var/covar matrices; see Figure 20).

All models for which retrospective analyses were performed displayed retrospective patterns (Figure 25). However, models in which separate recruitment deviations for males and females were estimated had smaller retrospective patterns.

Below, the fits to the data and estimated population processes for eight models are described. The data for all eight models were the same, however, the priors on natural mortality changed. Consequently, only the total likelihood of those models with the same prior on natural mortality can be directly compared. Individual likelihood components can be compared among models with the understanding that changing the weighting or data for one likelihood component influences others.

## Fits to data

## Survey biomass data

Fits to the survey mature male biomass were visually similar for all models for the majority of years in the the time series (Figure 26); models in which separate recruitment deviations for males and females were estimated fit the data significantly better than those that did not. (Table 11). Estimates of survey MMB in the final year ranged from 85.84 to 141.6 kt . All models underestimated the final year of observed survey MMB (198.384 kt).

Fits to the survey mature female biomass (MFB) changed markedly when separate recruitment deviations were estimated for males and females (Figure 26). Models in which priors on natural mortality were less informative also improved the fit. All models overestimated the final year of observed survey MFB (165.895 $\mathrm{kt})$.

## Growth data

A range of shapes of growth curve were estimated to fit the female growth increment data (Figure 27). Models in which the prior on natural mortality for mature females was less informative, but separate recruitment deviations were not estimated, fit the female growth data the best (Table 11). These models estimate a linear relationship between growth increment and pre-molt length. The shapes of the growth curves for males were generally similar, save the linear growth curve imposed by "Sep devs + loose + linear growth". Improved fits to the male growth data resulted from less informative priors on natural mortality, but, in contrast to females, so did estimating separate recruitment deviations (Table 11). The model in which a linear growth curve was fit ("Sep devs + loose + growth") was very unstable- only 2 of 70 jittered models had gradients less than 0.005 (and most were $\gg 1$ ).

## Catch data

Retained catch data were fit by all models well, with no visually discernible differences among models (Figure 28). Female discard data were fit adequately given the specified uncertainty (Figure 28 \& Table 11). Male discard data during the period for which data exist (early 1990s to the present) were well fit by every model with little visually discernible difference (Figure 28 ). Models in which separate recruitment deviations were estimated returned significantly lower likelihoods for male discard data (Table 11). Fits to the trawl data were adequate for all models given the uncertainty in the data (Figure 28).

## Size composition data

Retained catch size composition data were fit well by all models (Figure 29); total catch size composition data were similarly well fit (Figure 30). Trawl size composition data were generally well fit, with several exceptions
in certain years. All models performed similarly in fitting the trawl size composition data (Figure $31 \&$ Table 11).

Models that estimated separate recruitment deviations for males and females fit the BSFRF size composition data better than those that did not (Figure $32 \&$ Table 11). The number of males was generally underestimated by the industry survey in 2009 and overestimated by the NMFS survey, while the opposite pattern was seen for females. Fits to the 2010 survey size composition data were better than the 2009 fits. Models that estimated separate recruitment deviations for males and females fit the survey composition data better than those that did not (Figure 33, Figure 34, \& Table 11). The distribution of residuals for male and female survey composition data for the chosen model varied by sex. Female and male size composition data from the survey sum to 1 in a given year. Size composition data for females tended to be overestimated (Figure 35), whereas males tended to be underestimated (Figure 36).

## Estimated population processes and derived quantities

Population processes and derived quantities varied among models, sometimes widely. Projected MMB for 2018 ranged from 101.38 to 135.01 kt (Figure 37). In general, estimated fishing mortality in the recent past has been well below $\mathrm{F}_{35 \%}$, save the years 2012-2014, which were close to $\mathrm{F}_{35 \%}$ (Figure 38). Estimated MMB has been less than $\mathrm{B}_{35 \%}$ since 2010, and estimates from "Sep devs" suggest that the population may have been overfished in 2015 (Figure 38). Still, the estimated MMB is currently above MSST and is projected to exceed $\mathrm{B}_{35 \%}$ in the coming year.

Estimates of selectivity and catchability varied among models (Figure 39). Estimated catchability in both eras was lower for males than for females. In era 1 (1982-1988), catchability ranged from 0.31-0.52 for males; for females, it ranged from $0.35-0.75$. In era 2 (1989-present), catchability ranged from $0.48-0.78$ for males; for females, it ranged from $0.74-1$. Estimated size at $50 \%$ selection in the survey gear for era 1 ranged from $\sim 38 \mathrm{~mm}$ to $\sim 45 \mathrm{~mm}$ for both females and males. Size at $50 \%$ selection in the survey gear during era 2 ranged from 34 mm to 42 mm for females and 34 mm to 41 mm for males. BSFRF 'availability' curves varied widely from 2009 to 2010 and among models, with the availability of crab to the experimental survey generally increasing in 2010 (Figure 40).

The probability of maturing by size was dependent upon the strength of the prior on natural mortality. The probability of maturing at length for males when the prior was informative was less than scenarios in which the prior was less informative (Figure 41). In general, the shape of the curve representing the probability of maturing for both sexes was consistent, but the magnitude of the probabilities varied. For all models, the probability of maturing by size for female crab was $\sim 50 \%$ at $\sim 47.5 \mathrm{~mm}$ and increased to $100 \%$ at $\sim 60 \mathrm{~mm}$ (Figure 41). The probability of maturing for male crab was $\sim 15 \%$ to $20 \%$ at $\sim 60 \mathrm{~mm}$ and increased sharply to $50 \%$ at $\sim 97.5 \mathrm{~mm}$, and $100 \%$ at 107.5 mm . The region from 60 mm to 90 mm male carapace width displayed the largest differences in estimates of the probability of maturing among models.

Estimated fishing mortality in the directed fishery was similar for all models, except for in the most recent years. In those year, models that estimated separate recruitment deviations for males and females estimated higher fishing mortalities (Figure 42). Total and retained fishery selectivity was very similar for all models because of the weight put on the retained catch and its associated size composition data (Figure 42). Estimated size at $50 \%$ selection in the trawl fishery varied more than selectivity in the directed fishery, ranging from 108 - 113 mm (Figure 42). Size at $50 \%$ selection for discarded females was similar for all models (Figure 42).

Patterns in recruitment were similar for all models that estimated recruitment similarly (i.e. models that estimated a single vector of recruitment deviations vs. models that estimated a vector each for males and females). A period of high recruitment was observed in which 3 large cohorts passed through the population during the 1980s and into the early 1990s. Following that, a period of low recruitment persisted from the early 1990s to 2013. All models indicated a large (relative to the past) recruitment to the survey gear occurred in the last few years (Figure 43). Recruitment entering the model was placed primarily in the first three size bins (Figure 43). Stock recruitment relationships were not apparent between the estimates of MMB and recruitment for any model (Figure 43). Relationships were not apparent between mature female biomass and recruitment either (not shown).

Estimated natural mortality ranged from 0.27 to 0.35 for immature crab, 0.26 to 0.61 for mature male crab, and 0.345 to 1.04 for mature females (Table 10). Some of these estimates are markedly higher than previous estimates of M from the assessment and literature.

## F. Calculation of the OFL

## Methodology for OFL

The OFL was calculated using proxies for biomass and fishing mortality reference points and a sloped control rule. Proxies for biomass and fishing mortality reference points were calculated using spawner-per-recruit methods (e.g. Clark, 1991). After fitting the assessment model to the data and estimating population parameters, the model was projected forward 100 years using the estimated parameters under no exploitation to determine 'unfished' mature male biomass-per-recruit. Projections were repeated in which the bisection method was used to identify a fishing mortality that reduced the mature male biomass-per-recruit to $35 \%$ of the unfished level (i.e. $\mathrm{F}_{35 \%}$ and $\mathrm{B}_{35 \%}$ ). Calculations of $\mathrm{F}_{35 \%}$ were made under the assumption that bycatch fishing mortality was equal to the estimated average value.

Calculated values of $\mathrm{F}_{35 \%}$ and $\mathrm{B}_{35 \%}$ were used in conjunction with a control rule to adjust the proportion of $\mathrm{F}_{35 \%}$ that is applied based on the status of the population relative to $\mathrm{B}_{35 \%}$ (Amendment 24, NMFS).

$$
F_{O F L}= \begin{cases}\text { Bycatch } & \text { if } \frac{M M B}{M M B_{35}} \leq 0.25  \tag{2}\\ \frac{F_{35}\left(\frac{M M B}{\left.M M B_{35}-\alpha\right)}\right.}{1-\alpha} & \text { if } 0.25<\frac{M M B}{M M B_{35}}<1 \\ F_{35} & \text { if } M M B>M M B_{35}\end{cases}
$$

Where MMB is the projected mature male biomass in the current survey year after fishing at the $\mathrm{F}_{\text {OFL }}$, $\mathrm{MMB}_{35 \%}$ is the mature male biomass at the time of mating resulting from fishing at $\mathrm{F}_{35 \%}, \mathrm{~F}_{35 \%}$ is the fishing mortality that reduces the mature male biomass per recruit to $35 \%$ of unfished levels, and $\alpha$ determines the slope of the descending limb of the harvest control rule (set to 0.1 here).

## Calculated OFLs and interpretation

Maximum likelihood estimates of OFLs calculated for the suite presented models ranged from 29.74 to 79.54 kt (Figure 44 \& Table 12). Differences in OFLs were a result of differences in estimated MMB (see above), calculated $\mathrm{B}_{35 \%}$ (which ranged from 108.89 to 142.77 kt ), Table 12 ), $\mathrm{F}_{35 \%}$ (which ranged from 1.19 to 9.42 $\mathrm{yr}^{-1}$, Table 12), and $\mathrm{F}_{\text {OFL }}$ (which ranged from 0.88 to $9.42 \mathrm{yr}^{-1}$, Table 12).

## G. Calculation of the ABC

The acceptable biological catch (ABC) was set by subtracting a $20 \%$ buffer from the OFL to account for scientific uncertainty, which was recommended by the SSC.

## Author recommendations

Selecting an author preferred model was challenging. Models without separate recruitment deviations for males and females displayed large retrospective patterns in estimated MMB, a key determinant of the OFL. Models in which the prior for natural mortality was less informative fit the data best and not all of this improvement was derived from the decreased contribution of the prior to the likelihood. However, estimates of natural mortality from models with the least informative priors were unrealistic and the mid-range prior has little rationale for selection (though Murphy et al., (2018) suggest that natural mortality may be higher than currently assumed in the assessment). Still, given the confounding between natural mortality and recruitment (and other parameters) freeing recruitment up by estimating separate recruitment deviations by sex, but placing a strong prior on M are not very satisfying model assumptions. Estimates of female catchability equaling 1 in the survey are also likely unreasonable. Several models also still estimate a kink in the growth curve, in spite of what appears to be very linear data, however the linear growth model had convergence issues.

The model construction in which male and female recruitment deviations are separate and the prior on natural mortality is relatively uninformative ("Sep devs + loose M") is the most attractive of the presented models because it imposes fewer assumptions on the data without allowing most key parameters to stray into unbelievable territory. Further, the model that imposes linear growth in this model is even more attractive because the growth data are best fit by a linear model, but that model had serious convergence problems. Only $2 \%$ of models converged after jittering and there was a 40kt difference in the OFLs from the 2 converged models.

## H. Data gaps and research priorities

## Data sources

As many raw data sources as possible should be included in the assessment. Estimating parameters outside of the model and inputting them as 'known' artificially decreases the uncertainty represented in the standard errors and posteriors of management quantities. Weight at length data, data used to develop priors for natural mortality and maturity, and the selectivities calculated from the BSFRF data should be considered for inclusion in the model to comprehensively represent the uncertainty in management quantities. In addition to pulling as much data into the model as possible, continuing to standardize and automate the creation of data files from the survey and catch databases would be very useful given the short time frame of the assessment cycle.

Additional growth data for males would be useful because there are regions of pre-molt length for which we have no data. This is particularly important if the 'kinked' growth model is retained-if not, these data become less important.

## Modeling and weighting

In theory, we have data to inform all of the confounded processes. Catchability is informed by the BSFRF studies. Natural mortality is informed by the survey length composition data as a result of large portions of the population being unfished. Recruitment is also informed by the survey length composition data and growth is increasingly well characterized due to the efforts of the Kodiak lab. In spite of these data, just changing the prior on M can result in large changes in many different estimated population processes. This suggests that data weighting is a key hurdle to providing management advice using this assessment and needs to be carefully considered.

It is not clear in practice which parameters can be reliably estimated with the currently available data and assessment model. Different weightings of likelihood components can have drastic impacts on the management advice provided from an assessment. A close look at the way CVs, sample sizes, and other weighting factors
are calculated and their influence on assessment results could provide better understanding of how well the model is balanced. Simulations may be useful to understand both the estimability of the parameters in the current model with the current data and the impact of the weights assigned to different data sources. Standardization of the weighting schemes would also improve readability of the code (for example, some size composition data have both 'weights' and 'sample sizes').

## Scientific uncertainty

Natural mortality exerts a large influence over estimated management quantities and population processes (as shown above), but is poorly known. Tagging studies targeted at estimating natural mortality could be useful and could also shed light on the migration patterns, which could help us understand the impact of the fishery (e.g. centroids of large male abundance in the survey and catch do not match-is this because the crab are moving or because the fishery operates in a specific place? The answer to this question could influence priors on catchability.)

Similarly, establishing measures of reproductive capacity that include females, the spatial overlap of mature individuals, the role water temperature plays in biennial spawning, and the effectiveness of mating by size for males may allow for relationships between recruitment and mature biomass to be found (e.g. Murphy et al. 2017). In general, exploring the spatial dynamics of the population may allow for patterns and influences of the fishery and environment on the productivity of the stock to be more easily identified.

Previous analyses suggest that retrospective patterns may be a problem for the snow crab assessment (Szuwalski and Turnock, 2016), which was supported by this analysis. Retrospective patterns can result from unaccounted for time-varying processes in the population dynamics of the model (Hurtado et al., 2015). The retrospective patterns in MMB for snow crab appears to be at least partially a result of an large estimate of survey MMB in 2014 and the assumption of shared recruitment deviations between male and females. The large survey MMB may have caused by a change in catchability for that year and focused research on time-variation in important population processes for snow crab should be pursued to confront retrospective biases.

Additionally, moving to a designation of the ABC based on the standard errors or posterior distributions (similar to the p-star methods) rather than a flat percentage buffer may represent the uncertainty in the data better, but would require including more data sources into the estimation procedure.

## Style

Although the code has been trimmed considerably recently, legacy code and unused variables still exist within the assessment. Streamlining the code makes it more readable and reduces the probability of bugs. Most constants were migrated from the .TPL to the .CTL file, but parameter bounds have not yet been moved. Adjusting the manner in which output files are opened when evaluating MCMC output should also be implemented to avoid overwriting output files. A move to GMACs would obviate the need for these corrections, but the GMACs code still needs to be adapted to accommodate snow crab life history.

## I. Ecosystem Considerations

Historically, recruitment for snow crab could be divided into two periods via regime shift algorithms (e.g. Rodionov, 2004). Szuwalski and Punt (2013) reported that the shift in recruitment corresponded with a change in the winter Pacific Decadal Oscillation (Szuwalski and Punt, 2013), but also with a period of intense fishing mortality. The recent observed large recruitments may suggest a new 'regime' has begun.

Checking the new estimates of recruitment against the winter PDO (from Szuwalski and Punt, 2013) showed that the relationship has broken down with the addition of new data (which is a common phenomenon; Myers 2001). However, the PDO is highly correlated with the Arctic Oscillation (AO) and the AO is significantly
correlated with estimated snow crab recruitment (Figure 45). Negative values of the AO are associated with high pressure in the polar region and greater movement of polar air into lower latitudes. This relationship may be another clue in the search for mechanistic explanations for changes in snow crab recruitment.

Regime-based management strategies have been evaluated for snow crab, but found that only small improvements in long-term yield are derived from changing the target reference points based on a change point algorithm and those changes come at a higher risk of overfishing (Szuwalski and Punt, 2012). Given the uncertainty around whether or not the environment or the fishery precipitated changes in recruitment, the precautionary principle guides managers to assume it is the fishery. Spatial analyses of recruitment, mature biomass, environmental drivers, and the impact of the fishery may provide insight to the population dynamics of snow crab, but modeling techniques capable of fully-spatial stock assessment are only recently feasible. The most recent large recruitment events will likely divide the recruitment time series into three periods and present an intriguing opportunity for further study of the relationship between environmental variables and recruitment success.

## Appendix A: Model structure

## Population dynamics

Numbers of sex $s$ of shell condition $v$ and maturity state $m$ at length $l$ in the initial year of the assessment, $\mathrm{N}_{s, v, m, y=1, l}$, were calculated from an estimated vector of numbers at length $l$ by sex $s$ and maturity state $m$ for males, $\lambda_{s, m, l}$ and numbers at length $l$ by sex $s$ and shell condition $v$ for females (i.e. 2 vectors for each sex were estimated). Estimated vectors of initial numbers at length by maturity for females were calculated by splitting the estimated vectors at length by the observed proportion mature in the first year of the survey.

$$
N_{s, v, m, y=1, l}= \begin{cases}\Omega_{s, l}^{o b s} \lambda_{s, 1, l} & \text { if } \mathrm{v}=\text { new; } \mathrm{m}=\mathrm{mat}, \mathrm{~s}=\text { fem }  \tag{3}\\ 1-\Omega_{s, l}^{o b s} \lambda_{s, 1, l} & \text { if } \mathrm{v}=\text { new; } \mathrm{m}=\text { imat }, \mathrm{s}=\mathrm{fem} \\ \lambda_{s, 2, l} & \text { if } \mathrm{v}=\text { old; } \mathrm{m}=\mathrm{mat}, \mathrm{~s}=\mathrm{fem} \\ 0 & \text { if } \mathrm{v}=\text { old } ; \mathrm{m}=\text { imat }\end{cases}
$$

Initial numbers at length for males were all assumed to be new shell.

$$
N_{s, v, m, y=1, l}= \begin{cases}\lambda_{s, 1, l} & \text { if } \mathrm{v}=\text { new } ; \mathrm{m}=\text { mat }, \mathrm{s}=\text { male }  \tag{4}\\ \lambda_{s, 2, l} & \text { if } \mathrm{v}=\text { new; } \mathrm{m}=\text { imat }, \mathrm{s}=\text { male } \\ 0 & \text { if } \mathrm{v}=\text { old } ; \mathrm{m}=\text { mat }, \mathrm{s}=\text { male } \\ 0 & \text { if } \mathrm{v}=\text { old } ; \mathrm{m}=\text { imat }, \mathrm{s}=\text { male }\end{cases}
$$

The dynamics after the initial year were described by:

$$
N_{s, v, m, y+1, l}= \begin{cases}\Omega_{s, l} \kappa_{s, l^{\prime}} Q_{s, i m a t, y, l^{\prime}} X_{s, l^{\prime}, l} & \text { if } \mathrm{v}=\mathrm{new} ; \mathrm{m}=\mathrm{mat}  \tag{5}\\ 1-\Omega_{s, l} \kappa_{s, l^{\prime}} Q_{s, i m a t, y, l^{\prime}} X_{s, l^{\prime}, l}+\operatorname{Rec}_{y}^{\epsilon} \operatorname{Pr}_{l} & \text { if } \mathrm{v}=\mathrm{new} ; \mathrm{m}=\mathrm{imat} \\ Q_{s, m a t, y, l^{\prime}} & \text { if } \mathrm{v}=\mathrm{old} ; \mathrm{m}=\mathrm{mat} \\ \left(1-\kappa_{s, l^{\prime}}\right) Q_{s, i m a t, y, l^{\prime}} & \text { if } \mathrm{v}=\mathrm{old} ; \mathrm{m}=\mathrm{imat}\end{cases}
$$

Where $\Omega_{s, l}$ was the probability of maturing at length $l$ for sex $s$ (a freely estimated vector for both males and females constrained by penalties on smoothness and a prior in some scenarios), $\kappa_{s, l^{\prime}}$ was the probability of molting for an immature crab of sex $s$ at length $l^{\prime}$ (set to 1 for all immature crab), and $\mathrm{X}_{s, l, l}$, was the size transition matrix describing the probability of transitioning from size $l$ ' to size $l$ for sex $s$. $\mathrm{Q}_{s, m, y, l}$, was the number of crab of sex $s$, maturity state $m$, and length $l$ ' surviving natural and fishing mortality during year $y$ :

$$
\begin{equation*}
Q_{s, m, y, l}=\sum_{v} N_{s, v, m, y, l} l^{Z_{s, v, m, y, l}} \tag{6}
\end{equation*}
$$

Where $\mathrm{N}_{s, v, m, y, l}$ represented the numbers, $N$, of sex $s$ during year $y$ of shell condition $v$ and maturity state $m$ at length $l$. $\mathrm{Z}_{x, v, m, y, l}$ represented the total mortality experienced by the population and consisted of the sum of instantaneous rates of natural mortality by sex and maturity state, $\mathrm{M}_{s, m}$, and fishing mortality, $\mathrm{F}_{s, f, y, l}$ from each fishery. Each fishing mortality was subject to selectivity by length $l$, which varied between sexes $s$ and fisheries $f$ (and by year $y$ if specified). $\mathrm{M}_{s, m}$ was specified in the model and a multiplier $\gamma_{n a t M, m}$
was estimated subject to constraints (see Table 9; this formulation effectively specified a mean and standard deviation for a prior distribution for M$)$.

$$
\begin{equation*}
Z_{s, v, m, y, l}=\gamma_{n a t M, m} M_{s, m}+\sum_{f} S_{s, f, y, l} F_{s, f, y, l} \tag{7}
\end{equation*}
$$

Selectivities in the directed and bycatch fisheries were estimated logistic functions of size. Different selectivity parameters were estimated for females and males in the directed fisheries ( $\mathrm{S}_{f e m, d i r, l}$ and $\mathrm{S}_{\text {male,dir,l}}$, respectively), a single selectivity for both sexes was estimated for bycatch in the groundfish trawl fishery ( $\mathrm{S}_{\text {trawl, } l}$ ), and a retention selectivity was estimated for the directed fishery for males ( $\mathrm{R}_{d i r, l}$; all females were discarded).

$$
\begin{align*}
S_{\text {male }, \text { dir }, l} & \left.=\frac{1}{\left.1+e^{-S_{\text {slope }, m, d}\left(L_{l}-S_{50, m, d}\right.}\right)}\right)  \tag{8}\\
S_{\text {fem }, \text { dir }, l} & \left.=\frac{1}{\left.1+e^{-S_{\text {slope }, f, d}\left(L_{l}-S_{50, f, d}\right.}\right)}\right)  \tag{9}\\
S_{\text {trawl }, l} & =\frac{1}{\left.1+e^{-S_{\text {slope }, t}\left(L_{l}-S_{50, t}\right.}\right)}  \tag{10}\\
R_{\text {dir }, l} & \left.=\frac{1}{1+e^{-S_{\text {slope }, m, d}\left(L_{l}-S_{50, m, d}\right.}}\right) \tag{11}
\end{align*}
$$

Where $\mathrm{S}_{\text {slope,s,f }}$ was the slope of the logistic curve for sex $s$ in fishery $f$ and $\mathrm{S}_{50, s, f}$ was the length at $50 \%$ selection for sex $s$ in fishery $f$. Catches for all fisheries were modeled as pulse fisheries in which all catch was removed instantaneously (i.e. no natural mortality occurred during the fishery). Catch in fishery $f$ during year $y$ was calculated as the fraction of the total fishing mortality, $\mathrm{F}_{s, f, y, l}$, applied to a given sex $s$ in a fishery $f$ times the biomass removed by all fisheries for that sex.

$$
\begin{align*}
& C_{m a l e, d i r, y}=\sum_{l} \sum_{v} \sum_{m} w_{m a l e, l} \frac{R_{l} F_{\text {male }, \text { dir }, y, l}}{F_{\text {male }, \text { dir }, y, l+F_{\text {trawl }, y, l}}} N_{\text {male }, v, m, y, l} e^{-\delta_{y} M_{s, m}}\left(1-e^{-\left(F_{\text {male }, \text { dir }, y, l}+F_{\text {trawl }, y, l)}\right)}\right. \\
& C_{m a l e, t o t, y}=\sum_{l} \sum_{v} \sum_{m} w_{m a l e, l} \frac{F_{\text {male }, d i r, y, l}}{F_{\text {male }, d i r, y, l+F_{\text {trawl }, y, l}}} N_{\text {male }, v, m, y, l} e^{-\delta_{y} M_{s, m}}\left(1-e^{-\left(F_{\text {male }, \text { dir }, y, l}+F_{\text {trawl }, y, l}\right)}\right)  \tag{12}\\
& C_{f e m, d i r, y}=\sum_{l} \sum_{v} \sum_{m} w_{f e m, l} \frac{F_{f e m, d i r, y, l}}{F_{f e m, d i r, y, l+F_{t r a w l, y, l}}} N_{f e m, v, m, y, l} e^{-\delta_{y} M_{s, m}}\left(1-e^{-\left(F_{f e m, d i r, y, l}+F_{t r a w l, y, l}\right)}\right)  \tag{14}\\
& C_{m+f, t r a w l, y}=\sum_{s} \sum_{l} \sum_{v} \sum_{m} w_{s, l} N_{s, v, m, y, l} e^{-\delta_{y} M_{s, m}}\left(1-e^{-\left(F_{\text {trawl }, y, l}\right)}\right) \tag{15}
\end{align*}
$$

Where $\delta_{y}$ was the mid point of the fishery (all fisheries were assumed to occur concurrently and the midpoint was based on the directed fishery, which accounts for the vast majority of the fishing mortality) and $\mathrm{w}_{s, l}$ was the weight at length $l$ for sex $s$. Trawl data and discard data were entered into the model with an assumed mortality of $80 \%$ and $30 \%$, respectively. Fully-selected fishing mortality parameters for fishery $f$ were estimated as a logged average over a given time period ( $F_{a v g}^{l o g}$ ) with yearly deviations around that mean $\left(F_{d e v, y}^{l o g}\right)$.

$$
\begin{equation*}
F_{f, y}=e^{\left(F_{a v g, f}^{l o g}+F_{d e v, f, y}^{l o g}\right)} \tag{16}
\end{equation*}
$$

Selectivity for the survey was estimated for 2 eras in the base model: 1982-1988 and 1989-present. Selectivity was assumed to be logistic and separate parameters representing the length at which selection probability
equal $50 \%$ and $95 \%$ ( $\mathrm{s}_{50, s, e}$ and $\mathrm{s}_{95, s, e}$, respectively) were estimated for males and females in the third era (1989-present). Separate catchability coefficients ( $\mathrm{q}_{s, e}$ ) were estimated for males and females in all eras.

$$
\begin{equation*}
\left.S_{\text {surv }, s, l, e}=\frac{q_{s, e}}{1+e^{-\log (19) \frac{L_{l}-s_{50, s, e}}{s_{95, s, e}-s_{50, s, e}}}}\right) \tag{17}
\end{equation*}
$$

Survey selectivity was informed by experimental surveys during the years 2009 and 2010. A portion of the NMFS summer survey tows were accompanied by an industry vessel using nephrops trawls with an assumed selectivity of 1 for all size classes. To represent the proportion of the population covered by the experiment, a vector was freely estimated for males, $S_{y}^{\text {free }}$ (subject to a scaling parameter), and a logistic curve was estimated for females.

$$
S_{\text {ind }, s, l, y}= \begin{cases}\frac{q_{\text {ind }, s, y}}{\left.1+e^{-\log (19) \frac{L_{l}-s_{50, s, y}}{s_{95, s, y}-s_{50, s, y}}}\right)} & \text { if } \mathrm{s}=\text { female }  \tag{18}\\ q_{\text {ind }, s, y} S_{y}^{\text {free }} & \text { if } \mathrm{s}=\text { male }\end{cases}
$$

Based on this logic, after identifying the fraction of the crab at length covered by the experimental surveys, the length frequencies of the NMFS data collected simultaneously with the experimental trawls can be calculated by multiplying the numbers at length 'available' to the experimental trawls by the overall survey selectivity, $\mathrm{S}_{\text {surv,s,l,y }}$. The predicted numbers at length for the NMFS and industry data from the selectivity experiment were calculated by multiplying the respective selectivities by the survey numbers at length.

$$
\begin{equation*}
S_{n m f s, s, l, y}=S_{i n d, s, l, y} S_{s u r v, s, l, y} \tag{19}
\end{equation*}
$$

Mature male and female biomass (MMB and FMB, respectively) were fitted in the objective function and were the product of mature numbers at length during year $y$ and the weight at length, $\mathrm{w}_{s, l}$ :

$$
\begin{align*}
M M B_{y} & =\sum_{l, v} w_{\text {male }, l} N_{\text {male }, v, \text { mat }, y, l}  \tag{20}\\
F M B_{y} & =\sum_{l, v} w_{f e m, l} N_{\text {fem }, v, \text { mat }, y, l}  \tag{21}\\
w_{s, l} & =\alpha_{w t, s} L_{l}^{\beta_{w t, s}} \tag{22}
\end{align*}
$$

Mature biomass can be calculated for different time through out the year, in which case the numbers at length are decremented by the estimated natural mortality. Parameters $\alpha_{w t, s}$ and $\beta_{w t, s}$ were estimated outside of the assessment model and specified in the control file.

Molting and growth occur before the survey. Immature crab were assumed to molt every year with an estimated probability of molting to maturity based on length $l$ (in all the scenarios presented here, the probability of molting was 1 for all immature animals). For crab that do molt, the growth increment within the size-transition matrix, $\mathrm{X}_{s, l, l}$, was based on a piece-wise linear relationship between predicted pre- and post-molt length, ( $\hat{L}_{s, l}^{p r e d}$ and $\hat{L}_{s, l}^{p o s t}$, respectively) and the variability around that relationship was characterized by a discretized and renormalized gamma function, $\mathrm{Y}_{s, l, l}$.

$$
\begin{gather*}
X_{s, l, l^{\prime}}=\frac{Y_{s, l, l^{\prime}}}{\sum_{l^{\prime}} Y_{s, l, l^{\prime}}}  \tag{23}\\
Y_{s, l, l^{\prime}}=\left(\Delta_{l, l^{\prime}} \frac{L_{s, l^{\prime}-\left(\bar{L}_{l}-2.5\right)}^{\beta_{s}}}{L_{s, l}}=\alpha_{s}+\beta_{s, 1} L_{l}\right.  \tag{24}\\
\hat{L}_{s, l}^{p o s t, 1} \tag{25}
\end{gather*}
$$

$$
\begin{gather*}
\hat{L}_{s, l}^{p o s t, 2}=\alpha_{s}+\delta_{s}\left(\beta_{s, 1}-\beta_{s, 2}\right)+\beta_{s, 2} L_{l}  \tag{26}\\
\hat{L}_{s, l}^{p o s t}=\hat{L}_{s, l}^{p o s t, 1}\left(1-\Phi\left(\frac{L_{l}-\delta_{a, x}}{s t g r}\right)\right)+\hat{L}_{s, l}^{p o s t, 2}\left(\Phi\left(\frac{L_{l}-\delta_{a, x}}{s t g r}\right)\right)  \tag{27}\\
\Delta_{l, l^{\prime}}=\bar{L}_{l^{\prime}}+2.5-L_{l} \tag{28}
\end{gather*}
$$

$\hat{L}_{s, l}^{p o s t, 1}$ and $\hat{L}_{s, l}^{p o s t, 2}$ were predicted post-molt lengths from each piece of the piece-wise relationship, and $\Phi()$ was a cumulative normal distribution in which $\delta_{a, x}$ was an estimated change point. The model in which linear growth was estimated removed equations 26 and 27 from the model.

An average recruitment for the assessment period (1982-present) and yearly deviations around this average were estimated within the assessment for models in which only a single vector of recruitment deviations was estimated. The sex ratio of recruitment was assumed to be $50 / 50$ male to female. Each year's estimated recruitment was allocated to length bins based on a discretized and renormalized gamma function with parameters specified in the control file.

$$
\begin{gather*}
\operatorname{Rec}_{y}=e^{\left(\operatorname{Rec}_{a v g}+R e c_{d e v, y}\right)}  \tag{29}\\
\operatorname{Pr}_{l}=\frac{\left(\Delta_{1, l}\right)^{\alpha_{r e c} / \beta_{r e c}} e^{-\Delta_{1, l^{\prime}} / \beta_{r e c}}}{\sum_{l^{\prime}}\left(\Delta_{1, l^{\prime}}\right)^{\alpha_{r e c} / \beta_{r e c}} e^{\left(-\Delta_{1, l^{\prime}} / \beta_{r e c}\right)}} \tag{30}
\end{gather*}
$$

For models in which separate vectors of recruitment deviations were estimated for males and females, a separate average recruitment was also estimated (in log space). Each vector of deviations was also subject to a smoothing penalty, but were not linked directly in any way (e.g. priors on the ratio of estimated male to female average recruitment).

## Likelihood components

Three general types of likelihood components were used to fit to the available data (Table 13). Multinomial likelihoods were used for size composition data, log-normal likelihoods were used for indices of abundance data, and normal likelihoods were used for catch data, growth data, priors, and penalties. Multinomial likelihoods were implemented in the form:

$$
\begin{equation*}
L_{x}=\lambda_{x} \sum_{y} N_{x, y}^{e f f} \sum_{l} p_{x, y, l}^{o b s} \ln \left(\hat{p}_{x, y, l} / p_{x, y, l}^{o b s}\right) \tag{31}
\end{equation*}
$$

$\mathrm{L}_{x}$ was the likelihood associated with data component x , where $\lambda_{x}$ represented an optional additional weighting factor for the likelihood, $N_{x, y}^{e f f}$ was the effective sample sizes for the likelihood, $p_{x, y, l}^{o b s}$ was the observed proportion in size bin $l$ during year $y$ for data component $x$, and $\hat{p}_{x, y, l}$ was the predicted proportion in size bin $l$ during year $y$ for data component $x$. 10 multinomial likelihood components were included in the assessment (see Table 13 for descriptions, weighting factors, and effective sample sizes).

Iterative methods for determining appropriate effective samples sizes for composition data are suggested to avoid over-weighting the size composition data and washing out the signal from the indices of abundance. Although the code has the capability to implement these methods, they were not used for this assessment.

Log normal likelihoods were implemented in the form:

$$
\begin{equation*}
L_{x}=\lambda_{x} \sum_{y} \frac{\left(\ln \left(\hat{I}_{x, y}\right)-\ln \left(I_{x, y}\right)\right)^{2}}{2\left(\ln \left(C V_{x, y}^{2}+1\right)\right)} \tag{32}
\end{equation*}
$$

$L_{x}$ was the contribution to the objective function of data component $x, \lambda_{x}$ was any additional weighting applied to the component, $\hat{I}_{x, y}$ was the predicted value of quantity $I$ from data component $x$ during year $y$, $\mathrm{I}_{x, y}$ was the observed value of quantity $I$ from data component $x$ during year $y$ and $\mathrm{CV}_{x, y}$ was the coefficient of variation for data component $x$ during year $y .5 \log$ normal likelihood components were included in this assessment (see Table 13 for descriptions, weighting factors, and CVs).

Normal likelihoods were implemented in the form:

$$
\begin{equation*}
L_{x}=\lambda_{x} \sum_{y}\left(\hat{I}_{x, y}-I_{x, y}\right)^{2} \tag{33}
\end{equation*}
$$

$L_{x}$ was the contribution to the objective function of data component $x, \lambda_{x}$ was represents the weight applied to the data component (and can be translated to a standard deviation), $\hat{I}_{x, y}$ was the predicted value of quantity $I$ from data component $x$ during year $y, \mathrm{I}_{x, y}$ was the observed value of quantity $I$ from data component $x$ during year $y .12$ normal likelihood components were included in the base assessment (see Table 13 for descriptions, weighting factors, and translated standard deviations).

Smoothing penalties were also placed on some estimated vectors of parameters in the form of normal likelihoods on the second differences of the vector.

Table 11: Contribution to the objective function by individual likelihood component by modeling scenario. Values in columns after Model 0 are the likelihood contribution of Model 0 minus the likelihood contribution of the model in the column. Positive values represent improvements in fit. Note that some of the model scenarios involve changing the weightings of data sources which invalidate the comparison of likelihoods for a data source among models.

Table 12: Changes in management quantities for each scenario considered. Reported management quantities are median posterior values.

Table 15: Predicted mature male (MMB), mature female (FMB), and males $>101 \mathrm{~mm}$ biomass ( 1000 t ) and numbers (in millions) at the time of the survey from the chosen model. Columns 2-5 are subject to survey selectivity; columns 6-9 are the population values (i.e. the numbers at length are not modified by multiplying them by a selectivity curve-they are estimates of the underlying population). These are maximum likelihood estimates that will differ slightly from the median posterior values.

| Survey <br> year | FMB | MMB | Male $>101$ <br> biomass | Male $>101$ <br> (millions) | FMB | MMB | Male $>101$ <br> biomass | Male $>101$ <br> (millions) |

# BRISTOL BAY RED KING CRAB STOCK ASSESSMENT IN FALL 2018 

J. Zheng and M.S.M. Siddeek<br>Alaska Department of Fish and Game<br>Division of Commercial Fisheries<br>P.O. Box 115526<br>Juneau, AK 99811-5526, USA<br>Phone: (907) 465-6102<br>Fax: (907) 465-2604<br>Email: jie.zheng @alaska.gov

## Executive Summary

1. Stock: red king crab (RKC), Paralithodes camtschaticus, in Bristol Bay, Alaska.
2. Catches: The domestic RKC fishery began to expand in the late 1960s and peaked in 1980 with a catch of 129.95 million lbs ( $58,943 \mathrm{t}$ ). The catch declined dramatically in the early 1980s and remained at low levels during the last three decades. Catches during recent years until 2010/11 were among the high catches in last 15 years. The retained catch in 2017/18 was approximately 6.8 million lbs ( $3,094 \mathrm{t}$ ), below the catch in $2016 / 17$ ( 8.5 million lbs). The magnitude of bycatch from groundfish trawl and fixed gear fisheries has been stable and small relative to stock abundance during the last 10 years.
3. Stock biomass: Estimated mature biomass increased dramatically in the mid-1970s and decreased precipitously in the early 1980s. Estimated mature crab abundance had increased during 1985-2009 with mature females being about three times more abundant in 2009 than in 1985 and mature males being about two times more abundant in 2009 than in 1985. Estimated mature abundance has steadily declined since 2009.
4. Recruitment: Estimated recruitment was high during 1970s and early 1980s and has generally been low since 1985 (1979 year class). During 1984-2018, only in 1984, 1986, 1995, 1999, 2002 and 2005 were estimated recruitments above the historical average for 1976-2018. Estimated recruitment was extremely low during the last ten years.
5. Management performance:

Status and catch specifications ( $1,000 \mathrm{t}$ ) (scenario 18.0a):

| Year | MSST | Biomass <br> $(\mathbf{M M B})$ | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | $13.03^{\mathrm{A}}$ | $27.25^{\mathrm{A}}$ | 4.49 | 4.54 | 5.41 | 6.82 | 6.14 |
| $2015 / 16$ | $12.89^{\mathrm{B}}$ | $27.68^{\mathrm{B}}$ | 4.52 | 4.61 | 5.31 | 6.73 | 6.06 |
| $2016 / 17$ | $12.53^{\mathrm{C}}$ | $25.81^{\mathrm{C}}$ | 3.84 | 3.92 | 4.35 | 6.64 | 5.97 |
| $2017 / 18$ | $12.74^{\mathrm{D}}$ | $24.86^{\mathrm{D}}$ | 2.99 | 3.09 | 3.48 | 5.60 | 5.04 |
| $2018 / 19$ |  | $20.80^{\mathrm{D}}$ |  |  |  | 5.34 | 4.27 |

The stock was above MSST in 2017/18 and hence was not overfished. Overfishing did not occur.

Status and catch specifications (million lbs):

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | ---: | ---: | ---: | ---: | :---: |
| $2014 / 15$ | $28.7^{\mathrm{A}}$ | $60.1^{\mathrm{A}}$ | 9.99 | 10.01 | 11.92 | 15.04 | 13.53 |
| $2015 / 16$ | $28.4^{\mathrm{B}}$ | $61.0^{\mathrm{B}}$ | 9.97 | 10.17 | 11.71 | 14.84 | 13.36 |
| $2016 / 17$ | $27.6^{\mathrm{C}}$ | $56.9^{\mathrm{C}}$ | 8.47 | 8.65 | 9.59 | 14.63 | 13.17 |
| $2017 / 18$ | $28.1^{\mathrm{D}}$ | $54.8^{\mathrm{D}}$ | 6.60 | 6.82 | 7.67 | 12.35 | 11.11 |
| $2018 / 19$ |  | $45.9^{\mathrm{D}}$ |  |  |  | 11.76 | 9.41 |

## A. Summary of Major Changes

## 1. Change to management of the fishery: None.

## 2. Changes to the input data:

a. Updated summer trawl survey data and directed pot fisheries catch and bycatch data through 2018.
b. Updated groundfish fisheries bycatch data during 2013-2017.

## 3. Changes to the assessment methodology:

a. Correcting two coding errors that result in overweighting small size length composition data of NMFS surveys and underweighting BSFRF survey biomass. These two errors were discovered recently by Dr. Andre Punt while working on GMACS. Combinations of these two errors make the model fit the NMFS survey data a little better and fit the BSFRF data a little worse. Comparison of the model results with the errors and without the errors are showed in survey biomass fits and absolute mature male biomass. The two errors do not affect past TACs and fishery.
b. Estimated recruitment in the terminal year is not used for estimating $B_{35 \%}$. That is, the mean recruitment from 1984-2017 is used for estimating $B_{35 \%}$.
c. For the directed pot fishery, the model fits total observer male biomass and length compositions, instead of discarded male biomass and length compositions. Observers will not separate retained and discarded legal males in the directed pot fishery from now on.
d. Analyses of terminal year of recruitment and dynamic $\mathrm{B}_{0}$ (see Appendix C).
e. Six model scenarios are compared in this report (See Section E.3.a for details):

Scenario 2b: the scenario 2b in the SAFE report in September 2017 with correction of the two errors mentioned in (a) above. This scenario assumes that BSFRF survey capture probabilities are 1.0 for all length groups. Under this assumption, NMFS survey selectivities are the products of crab availabilities (equal to BSFRF survey selectivities) and NMFS survey capture probabilities. A survey capture probability for a length group is simply defined as the proportion of the crab in the length group within the area-swept that is caught by the survey net. Also, groundfish fisheries bycatch is separated into trawl fisheries and fixed gear fisheries.

Scenario 2b-old: the scenario 2b in the SAFE report in September 2017 without two error corrections. The purpose to include this scenario is to compare it with scenario $2 b$ to examine the impacts of the two errors on the results.
Scenario 18.0: renamed from scenario 2bn1 in May 2018 with some changes based on the requests of CPT and SSC and the same as scenario 2 b except with differences: (1) the total observer male biomass and total observer male length composition data in the directed pot fishery are used to replace discarded male biomass and discarded male length composition data, (2) total male selectivity and retained proportions in the directed pot fishery are used to replace retained selectivity and discarded male selectivity, and (3) due to high grading problems in some years since rationalization, two logistic curves are estimated for retained proportions: one before rationalization (before 2005) and another after 2004.

Scenario 18.0a: the same as scenario 18.0 except with equal annual effective sample sizes of male and female length compositions. Annual effective sample sizes with scenario 18.0 may be different between male and female length composition data.

Scenario 18.0b: renamed from scenario 2 bn 2 in May 2018 with some changes based on the requests of CPT and SSC and the same as scenario 18.0 except that only one logistic curve is estimated for all years for retained proportions and annual retention adjusted factors are estimated to modify retained proportions for years after 2004.
Scenario 18.0c: the same as scenario 18.0 except with the differences of total male selectivity and retained proportions in the directed pot fishery: (1) one logistic curve for total male selectivity is estimated with annual deviations of length at $50 \%$ selectivity parameter ( $L_{50}^{\text {dir,tot }}$ ) and (2) another logistic curve is estimated for all years for retained proportions and for years after 2004 with annual deviations of length at $50 \%$ retained proportion parameter ( $L_{50}^{\text {ret }}$ ). Similar to scenario 18.0 b, after 2004, annual deviations are used to deal with annual high gradings

## 4. Changes to assessment results:

The population biomass estimates in 2018 are lower than those in 2017. Among the six scenarios, model estimated relative survey biomasses are very similar. The absolute mature male biomass estimates are higher for scenarios 18.0, 18.0a, 18.0b and 18.0c than for scenarios 2 b and 2 b -old during recent years. The model fits to BSFRF survey biomass are similar among six scenarios. The absolute mature male biomass estimates between scenarios 2 b and 2 b -old are very close: average relative error of $-1.6 \%$ and average absolute relative error of $7.5 \%$, and during the period covering the BSFRF survey data (2006-2017), relative errors ranging from $-10.4 \%$ to $6.4 \%$. Because of overweighting NMFS survey small length composition data and underweighting BSFRF survey biomass, scenario 2b-old fits the NMFS survey data better than other scenarios. We recommend scenario 18.0 or scenario 18.0a for overfishing definition for September 2018 because the results are hardly different among scenarios $18.0,18.0 \mathrm{a}, 18.0 \mathrm{~b}$ and 18.0 c and these two scenarios have the least number of estimated parameters. Scenario $2 b$ will be discontinued next year due to changes in data collection.

The recruitment breakpoint analysis (Appendix B) estimates 1986 as the breakpoint brood year, or 1992 recruitment year in May 2017. Terminal year recruitment analysis suggests the estimated recruitment in the last terminal year should not be used for estimating $B_{35 \%}$.

## B. Responses to SSC and CPT Comments

## 1. Responses to the most recent two sets of SSC and CPT comments on assessments in general:

CPT and SSC Comments (from January and February 2018)
Conduct a dynamic BO analysis and a retrospective analysis of terminal years of recruitment for the CPT meeting of May 2018.

Response: These two analyses are presented in this draft report (see retrospective results and Appendix C).

CPT comments (from January 2018)
"The CPT requested for the May 2018 meeting that assessment authors evaluate the impacts associated with discontinuing the collecting of information on legal retention status by crab observers. In addition, authors were encouraged to evaluate alternative discard calculations and/or suggest alternative methods for the determination of legal male retention status. It was also suggested that stock assessment authors outline for the CPT how legal not retained information is used or addressed in stock assessments."

Response: Four approaches (scenarios 18.0, 18.0a, 18.0b, and 18.0c) to deal with this issue are presented in this draft report.

## 2. Responses to the most recent two sets of SSC and CPT comments specific to this assessment:

## Response to CPT Comments (from September 2017):

"Look at the weighting again for this assessment: it is still based on multiplicative lambda's."
Response: Corresponding CV values are provided for the lambda values in this SAFE report.
"The difficulties achieving convergence need to be explored: they are unexpected and concerning."

Response: Yes, it is a concern. At the September 2017 CPT meeting, Jack Turnock mentioned that he had similar problems with the snow crab model. This could be parameter confounding or initial value problems.
"Jittering initial parameter values was not used in this assessment, but may be useful in evaluating convergence issues."

Response: Agreed. We used jittering before and may use it in the future.
"The tensions in the assessment data leading to estimates of NMFS survey $Q$ at 1 need to be identified and approaches to deal with them need to be developed."

Response: Correcting the error of underweighting BSFRF survey biomass help reducing estimated Q values somewhat. There may be several causes to explain this: (1) M and Q are confounded, (2) the sharp decline of abundance in the early 1980s may make estimated Q higher, and (3) few small crab were caught in the survey during the most recent 10 or more years, causing small estimated survey logistic curve values for the small size classes; for a given length, the overall selectivity value (combined catchability and logistic curve value) is $Q$ times logistic curve value, not just $Q$.

In May 2018, we did several runs to explore Q values: (1) for scenario 2b, estimated Qs are 0.97, 0.95 , and 0.93 with base M of $0.18,0.22$ and 0.3 ; (2) starting the model in 1985 for scenario 2 b , resulting in scenario 2 b 85 , Q is estimated as 0.91 , which fits the BSFRF survey biomass very well (see the results for scenario 2 b 85 in this draft SAFE report); (3) starting the model in 1985 for scenario 2 c with a fixed M of 0.18 , resulting in scenario $2 \mathrm{c} 85, \mathrm{Q}$ is estimated as 0.92 . These runs were with the error of underweighting BSFRF survey biomass. After correcting the error, estimated Q values would be smaller than the values here; for example, estimated Q value is 0.91 with scenario 2 b in this report.
"The assessment document needs to be updated to reflect changes in the 2016 BSFRF estimate in the main section of text, not just in the Executive Summary."

Response: This was done in 2017 SAFE report.
"Provide an explanation of why Equation A4 (catch in the directed fishery) is correct (or correct it if it is wrong)."

Response: The equation A4 (below) is correct. It is a simple equation under the assumption of pulse fishing. Total abundance is reduced by natural mortality to the mid-point of the directed pot fishing and then total fishing mortality is applied to the remaining abundance to get catch. For females, it is female bycatch. For males, the retained catch and bycatch are then separated by their selectivity proportions. The Tanner crab fishery and groundfish fisheries are assumed to be pulse fishing and occur after the directed fishery.
$G_{l, t}^{s}=\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-y_{t} M_{i}^{s}}\left(1-e^{-F_{l, t}^{s}}\right)$

## Response to CPT Comments (from May 2018):

"1) fitting the total catch estimated from at-sea observer data and total retained catch without incorporating the "subtraction" method for estimating legal discards,"

Response: Done for scenarios 18.0, 18.0a, 18.0b and 18.0c.
"2) incorporating time varying fishery selectivity and annual retained proportions,"
Response: Scenarios 18.0, 18.0b and 18.0c address this.
"3) the recruitment in terminal year should not be used for estimating B35\% (i.e., mean recruitment is estimated from recruitments from 1984 to endyear - 1)."

Response: Done for all scenarios.

## Response to SSC Comments specific to this assessment (from October 2017):

"The SSC reiterates its request from June 2017 for the BBRKC author and CPT to objectively define the terminal year of recruitment to include in reference point calculations in this and other crab assessments, and again requests that the author use the breakpoint analysis applied for Tanner crab to BBRKC to evaluate whether there was a detectable break in production in 2006. The SSC looks forward to the outcomes of a more comprehensive discussion on this topic at the January 2018 CPT meeting."

Response: Analysis of terminal year of recruitment is included in this draft SAFE report. Based on the results, we recommend not including the recruitment in the most recent year. Breakpoint analysis was done in May 2017, which includes brood years only up to 2005. We will repeat the breakpoint analysis in May 2019 to detect brood year 2006 when we get one more data point.
"This assessment uses the number of lengths measured as a starting point for input sample sizes. The SSC recommends following the approach of other crab and groundfish stocks in using the number of stations or pots sampled as a better proxy for statistical sample size given the frequently very high correlation among individuals within a single sample."

Response: Right now for crab stocks, only the Aleutian Islands golden king crab model does not use the number of lengths measured as a starting point for input sample sizes. The golden king crab model uses only directed fishery length composition data, so it is easy for the model to use boat-days for a starting point for effective sample sizes. The Bristol Bay red king crab model includes length composition data from the trawl survey, directed pot fishery, Tanner crab fishery bycatch, groundfish trawl bycatch, and groundfish fixed gear bycatch. It is difficult to find measurement units of sample sizes that are comparable. The number of survey hauls will be almost constant over time, which is difficult to compare with number of pots, or boat-days, or trips. Snow and Tanner crab models have the same problem. Hopefully we can learn from the groundfish stock model approaches and find a better way to deal with sample sizes in the future.
"More research on catchability is needed, including review of existing camera work from BSFRF surveys that may shed light on crab behavior in response to trawl gear. The SSC provided some comments on new research using modifications of the BSFRF Model under the subsection "Crab Bycatch" earlier in this report."

Response: We agree with these suggestions for needed research. Analysis of camera work from BSFRF surveys will be helpful, especially on the herding effects of BSFRF surveys.
"The CPT suggested that large catches that drove the stock down in the early 1980s could drive the fits, resulting in an estimate of $q$ near 1.0. On this basis, other evaluation of $q$ could include investigating the effect of the period of historical decline (perhaps by down-weighting it) on more
recent estimates of catchability, or fitting a research model fit to BBRKC with only data after the stock collapse in the early 1980s. "
"The SSC noted that historical modelling was conducted using relatively simple catch-survey analysis (Collie and Kruse 1998; Can. Spec. Publ. Fish. Aquat. Sci. 125: 73-83). This might provide another tool for exploring why current estimates of catchability are so close to 1.0."

Response: There may be several causes to explain Q value close to or higher than 1.0: (1) M and Q are confounded, (2) the sharp decline of abundance in the early 1980s may make estimated Q higher and (3) few small crab were caught in the survey during the most recent 10 or more years, causing small estimated survey logistic curve values for the small size classes; for a given length, the overall selectivity value (combined catchability and logistic curve value) is Q times logistic curve value, not just Q.

We did several runs to explore Q values in May 2018: (1) for scenario 2b, estimated Qs are 0.97, 0.95 , and 0.93 with base M of $0.18,0.22$ and 0.3 ; (2) starting the model in 1985 for scenario 2 b , resulting in scenario 2 b 85 , Q is estimated as 0.91 , which fits the BSFRF survey biomass very well (see the results for scenario 2 b 85 in this draft SAFE report); (3) starting the model in 1985 for scenario 2c with a fixed M of 0.18 , resulting in scenario 2 c 85 , Q is estimated as 0.92 . After correcting the error that underweights BSFRF survey biomass, estimated Q values would be smaller than the values here; for example, estimated $Q$ value is 0.91 with scenario $2 b$ in this report.

The catch-survey analysis (Collie and Kruse 1998; Can. Spec. Publ. Fish. Aquat. Sci. 125: 73-83) is a simple way to explore Q and M relationships. With similar M values as our model, Q is estimated to be 0.95 by Collie and Kruse (1998); however, with a constant M of 0.36 , Q is estimated to be 1.01 .
"The SSC is also looking forward to continued development of the Gmacs model for BBRKC during 2018."

Response: We are looking forward to the day of moving over to GMACS too.

## Response to SSC Comments specific to this assessment (from June 2018):

"to not use the subtraction method moving forward."
Response: Agree and no subtraction method from now on.
"The SSC also requests that the authors investigate whether groundfish discard information is available for fixed gear prior to 2010. In addition, the document uses inconsistent terminology for pot gear and fixed gear (particularly on figure and table headings), as well as groundfish gear versus crab gear, and the associated mortality rates. The SSC requests that the authors check the document for consistent use of these terms."

Response: We did some preliminary search on groundfish bycatch data and found that the data from 1991 to 2009 have been added to the NMFS database. During these years, fixed gear bycatch is an average of $22.6 \%$ of total groundfish bycatch. Due to time constraint, we will not separate
groundfish bycatch into trawl and fixed gear bycatch before 2009 for this CPT meeting (September 2018) and will sort out these data and use them in the CPT meeting in May 2019.

We went through our SAFE report to check for consistent use of gear terms and corrected them as necessary.

## C. Introduction

## 1. Species

Red king crab (RKC), Paralithodes camtschaticus, in Bristol Bay, Alaska.

## 2. General distribution

Red king crab inhabit intertidal waters to depths >200 m of the North Pacific Ocean from British Columbia, Canada, to the Bering Sea, and south to Hokkaido, Japan, and are found in several areas of the Aleutian Islands, eastern Bering Sea, and the Gulf of Alaska.

## 3. Stock Structure

The State of Alaska divides the Aleutian Islands and eastern Bering Sea into three management registration areas to manage RKC fisheries: Aleutian Islands, Bristol Bay, and Bering Sea (Alaska Department of Fish and Game (ADF\&G) 2012). The Bristol Bay area includes all waters north of the latitude of Cape Sarichef ( $54^{\circ} 36^{\prime} \mathrm{N}$ lat.), east of $168^{\circ} 00^{\prime} \mathrm{W}$ long., and south of the latitude of Cape Newenham ( $58^{\circ} 39^{\prime} \mathrm{N}$ lat.) and the fishery for RKC in this area is managed separately from fisheries for RKC outside of this area; i.e., the red king crab in the Bristol Bay area are assumed to be a separate stock from red king crab outside of this area. This report summarizes the stock assessment results for the Bristol Bay RKC stock.

## 4. Life History

Red king crab have a complex life history. Fecundity is a function of female size, ranging from several tens of thousands to a few hundreds of thousands (Haynes 1968; Swiney et al. 2012). The eggs are extruded by females, fertilized in the spring, and held by females for about 11 months (Powell and Nickerson 1965). Fertilized eggs are hatched in the spring, most during April-June (Weber 1967). Primiparous females are bred a few weeks earlier in the season than multiparous females.

Larval duration and juvenile crab growth depend on temperature (Stevens 1990; Stevens and Swiney 2007). Male and female RKC mature at 5-12 years old, depending on stock and temperature (Loher et al. 2001; Stevens 1990) and may live >20 years (Matsuura and Takeshita 1990). Males and females attain a maximum size of 227 and 195 mm carapace length (CL), respectively (Powell and Nickerson 1965). Female maturity is evaluated by the size at which females are observed to carry egg clutches. Male maturity can be defined by multiple criteria including spermataphore production and size, chelae vs. carapace allometry, and participation in mating in situ (reviewed by Webb 2014). For management purposes, females $>89 \mathrm{~mm}$ CL and males $>119 \mathrm{~mm}$ CL are assumed to be mature for Bristol Bay RKC. Juvenile RKC molt multiple times per year until age 3 or 4 ; thereafter, molting continues annually in females for life and in males until maturity. Male molting frequency declines after attaining functional maturity.

## 5. Fishery

The RKC stock in Bristol Bay, Alaska, supports one of the most valuable fisheries in the United States. A review of the history of the Bristol Bay RKC fishery is provided in Fitch et al. (2012) and Otto (1989). The Japanese fleet started the fishery in the early 1930s, stopped fishing from 1940 to 1952, and resumed the fishery from 1953 until 1974. The Russian fleet fished for RKC from 1959 to 1971. The Japanese fleet employed primarily tanglenets with a very small proportion of catch from trawls and pots. The Russian fleet used only tanglenets. United States trawlers started fishing Bristol Bay RKC in 1947, but the effort and catch declined in the 1950s. The domestic RKC fishery began to expand in the late 1960s and peaked in 1980 with a catch of 129.95 million lbs (58,943 t), worth an estimated $\$ 115.3$ million ex-vessel value. The catch declined dramatically in the early 1980 s and has remained at low levels during the last two decades (Table 1). After the early 1980s stock collapse, the Bristol Bay RKC fishery took place during a short period in the fall (usually lasting about a week) with the catch quota based on the stock assessment conducted the previous summer (Zheng and Kruse 2002). Beginning with the 2005/2006 season, new regulations associated with fishery rationalization resulted in an increase in the duration of the fishing season (October 15 to January 15). With the implementation of crab rationalization, historical guideline harvest levels (GHL) were changed to a total allowable catch (TAC). Before rationalization, the implementation errors were quite high for some years and total actual catch from 1980 to 2007 was about $6 \%$ less than the sum of GHL/TAC over that period.

## 6. Fisheries Management

King and Tanner crab stocks in the Bering Sea and Aleutian Islands are managed by the State of Alaska through a federal king and Tanner crab fishery management plan (FMP). Under the FMP, management measures are divided into three categories: (1) fixed in the FMP, (2) frame worked in the FMP, and (3) discretion of the State of Alaska. The State of Alaska is responsible for determining and establishing the GHL/TAC under the framework in the FMP.
Harvest strategies for the Bristol Bay RKC fishery have changed over time. Two major management objectives for the fishery are to maintain a healthy stock that ensures reproductive viability and to provide for sustained levels of harvest over the long term (ADF\&G 2012). In attempting to meet these objectives, the GHL/TAC is coupled with size-sex-season restrictions. Only males $\geq 6.5$-in carapace width (equivalent to $135-\mathrm{mm}$ carapace length, CL ) may be harvested and no fishing is allowed during molting and mating periods (ADF\&G 2012). Specification of TAC is based on a harvest rate strategy. Before 1990, harvest rates on legal males were based on population size, abundance of prerecruits to the fishery, and postrecruit abundance, and rates varied from less than $20 \%$ to $60 \%$ (Schmidt and Pengilly 1990). In 1990, the harvest strategy was modified, and a $20 \%$ mature male harvest rate was applied to the abundance of mature-sized ( $\geq 120-$ mm CL) males with a maximum $60 \%$ harvest rate cap of legal ( $\geq 135-\mathrm{mm}$ CL) males (Pengilly and Schmidt 1995). In addition, a minimum threshold of 8.4 million mature-sized females ( $\geq 90-\mathrm{mm}$ CL) was added to existing management measures to avoid recruitment overfishing (Pengilly and Schmidt 1995). Based on a new assessment model and research findings (Zheng et al. 1995a, 1995b, 1997a, 1997b), the Alaska Board of Fisheries adopted a new harvest strategy in 1996. That strategy had two mature male harvest rates: $10 \%$ when effective spawning biomass (ESB) is between 14.5 and 55.0 million lbs and $15 \%$ when ESB is at or above 55.0 million lbs (Zheng et al. 1996). The maximum harvest rate cap of legal males was changed from $60 \%$ to $50 \%$. A threshold of 14.5 million lbs of ESB was also added. In 1997, a minimum threshold of 4.0 million lbs was established as the minimum GHL for opening the fishery and maintaining fishery manageability
when the stock abundance is low. The Board modified the current harvest strategy by adding a mature harvest rate of $12.5 \%$ when the ESB is between 34.75 and 55.0 million lbs in 2003 and eliminated the minimum GHL threshold in 2012. The current harvest strategy is illustrated in Figure 1.

## D. Data

## 1. Summary of New Information

The NMFS and BSFRF trawl survey data were updated to include the 2018 survey data.
Catch and biomass data were updated to 2017/18. Groundfish fisheries bycatch data during 20132017 were updated.

Data types and ranges are illustrated in Figure 2.

## 2. Catch Data

Data on landings of Bristol Bay RKC by length and year and catch per unit effort from 1960 to 1973 were obtained from annual reports of the International North Pacific Fisheries Commission (Hoopes et al. 1972; Jackson 1974; Phinney 1975) and from the ADF\&G from 1974 to 2017. Bycatch data are available starting from 1990 and were obtained from the ADF\&G observer database and reports (Gaeuman 2013). Sample sizes for catch by length and shell condition are summarized in Table 2. Relatively large samples were taken from the retained catch each year. Sample sizes for trawl bycatch were the annual sums of length frequency samples in the National Marine Fisheries Service (NMFS) database.

## (i). Catch Biomass

Retained catch and estimated bycatch biomasses are summarized in Table 1 and illustrated in Figure 2. Retained catch and estimated bycatch from the directed fishery include the general, open-access fishery (prior to rationalization), or the individual fishery quota (IFQ) fishery (after rationalization), as well as the Community Development Quota (CDQ) fishery and the ADF\&G cost-recovery harvest. Starting in 1973, the fishery generally occurred during the late summer and fall. Before 1973, a small portion of retained catch in some years was caught from April to June. Because most crab bycatch from the groundfish trawl fisheries occurred during the spring, the years in Table 1 are one year less than those from the NMFS trawl bycatch database to approximate the annual bycatch for reporting years defined as July 1 to June 30; e.g., year 2002 in Table 1 for trawl bycatch corresponds to what is reported for year 2003 in the NMFS database. Catch biomass is shown in Figure 3. Bycatch data for the cost-recovery fishery before 2006 were not available. In this report, pot fisheries include both the directed fishery and RKC bycatch in the Tanner crab pot fishery and trawl fisheries are groundfish trawl fisheries.

## (ii). Catch Size Composition

Retained catch by length and shell condition and bycatch by length, shell condition, and sex were obtained for stock assessments. From 1960 to 1966, only retained catch length compositions from the Japanese fishery were available. Retained catches from the Russian and U.S. fisheries were assumed to have the same length compositions as the Japanese fishery during this period. From 1967 to 1969, the length compositions from the Russian fishery were assumed to be the same as those from the

Japanese and U.S. fisheries. After 1969, foreign catch declined sharply and only length compositions from the U.S. fishery were used to distribute catch by length.

## (iii). Catch per Unit Effort

Catch per unit effort (CPUE) is defined as the number of retained crab per tan (a unit fishing effort for tanglenets) for the Japanese and Russian tanglenet fisheries and the number of retained crab per potlift for the U.S. fishery (Table 1). Soak time, while an important factor influencing CPUE, is difficult to standardize. Furthermore, complete historical soak time data from the U.S. fishery are not available. Based on the approach of Balsiger (1974), all fishing effort from Japan, Russia, and U.S. were standardized to the Japanese tanglenet from 1960 to 1971, and the CPUE was standardized as crab per tan. Except for the peak-to-crash years of late 1970s and early 1980s the correspondence between U.S. fishery CPUE and area-swept survey abundance is poor (Figure 4). Due to the difficulty in estimating commercial fishing catchability and crab availability to the NMFS annual trawl survey data, commercial CPUE data were not used in the model.

## 3. NMFS Survey Data

The NMFS has performed annual trawl surveys of the eastern Bering Sea since 1968. Two vessels, each towing an eastern otter trawl with an 83 ft headrope and a 112 ft footrope, conducted this multispecies, crab-groundfish survey during the summer. Stations were sampled in the center of a systematic 20 X 20 nm grid overlaid in an area of $\approx 140,000 \mathrm{~nm}^{2}$. Since 1972 , the trawl survey has covered the full stock distribution except in nearshore waters. The survey in Bristol Bay occurs primarily during late May and June. Tow-by-tow trawl survey data for Bristol Bay RKC during 1975-2017 were provided by NMFS.

Abundance estimates by sex, carapace length, and shell condition were derived from survey data using an area-swept approach (Figures 5a and 5b). Spatial distributions of crab from the standard trawl surveys during recent years are shown in Appendix B. Until the late 1980s, NMFS used a post-stratification approach, but subsequently treated Bristol Bay as a single stratum; the estimates shown for Bristol Bay in Figures 4 and 5 were made without post-stratification. If multiple tows were made for a single station in a given year, the average of the abundances from all tows within that station was used as the estimate of abundance for that station. The new time series since 2015 discards all "hot spot" tows. We used the new area-swept estimates provided by NMFS in 2018.

In addition to standard surveys, NMFS also conducted some surveys after the standard surveys to better assess mature female abundance. In addition to the standard surveys conducted in early June (late May to early June in 1999 and 2000), a portion of the distribution of Bristol Bay RKC was resurveyed in 1999, 2000, 2006-2012, and 2017. Resurveys performed in late July, about six weeks after the standard survey, included 31 stations (1999), 23 stations (2000), 31 stations (2006, 1 bad tow and 30 valid tows), 32 stations (2007-2009), 23 stations (2010) and 20 stations (2011 and 2012) with high female density. The resurveys were necessary because a high proportion of mature females had not yet molted or mated when sampled by the standard survey. Differences in area-swept estimates of abundance between the standard surveys and resurveys of these same stations are attributed to survey measurement errors or to seasonal changes in distribution between survey and resurvey. More large females were observed in the resurveys than during the standard surveys in 1999 and 2000 because most mature females had not molted prior to the standard surveys. As in 2006, area-swept estimates of males >89 mm CL, mature males, and legal males within the 32 resurvey stations in 2007
were not significantly different ( $P=0.74,0.74$ and 0.95 ; paired $t$-test of sample means) between the standard survey and resurvey tows. However, similar to 2006, area-swept estimates of mature females within the 32 resurvey stations in 2007 were significantly different ( $P=0.03$; paired $t$-test) between the standard survey and resurvey tows. Resurvey stations were close to shore during 2010-2012, and mature and legal male abundance estimates were lower for the re-tow than the standard survey. Following the CPT recommendation, we used the standard survey data for male abundance estimates and only the resurvey data, plus the standard survey data outside the resurveyed stations, to assess female abundances during these resurvey years.

## 4. Bering Sea Fisheries Research Foundation Survey Data

The BSFRF conducted trawl surveys for Bristol Bay RKC in 2007 and 2008 with a small-mesh trawl net and 5-minute tows. The surveys occurred at similar times as the NMFS standard surveys and covered about $97 \%$ of the Bristol Bay area. Few Bristol Bay RKC were found outside of the BSFRF survey area. Because of the small mesh size, the BSFRF surveys were expected to catch more of RKC within the swept area. Crab abundances of different size groups were estimated by the kriging method. Mature male abundances were estimated to be 22.331 in 2007 and 19.747 million in 2008 with respective CVs of 0.0634 and 0.0765 . BSFRF also conducted a side-by-side survey concurrent with the NMFS trawl survey during 2013-2016 in Bristol Bay. In May 2017, survey biomass and size composition estimates from 2016 BSFRF side-by-side trawl survey data were updated. Total survey biomass decreased from $87,725.1 \mathrm{t}$ initially estimated in September 2016 to $77,815.7 \mathrm{t}$ in the final estimate in May 2017, about $11.3 \%$ reduction. The initial estimate mistakenly included the tows conducted in the recruitment study.

## E. Analytic Approach

## 1. History of Modeling Approaches

To reduce annual measurement errors associated with abundance estimates derived from the areaswept method, ADF\&G developed a length-based analysis (LBA) in 1994 that incorporates multiple years of data and multiple data sources in the estimation procedure (Zheng et al. 1995a). Annual abundance estimates of the Bristol Bay RKC stock from the LBA have been used to manage the directed crab fishery and to set crab bycatch limits in the groundfish fisheries since 1995 (Figure 1). An alternative LBA (research model) was developed in 2004 to include small size groups for federal overfishing limits. The crab abundance declined sharply during the early 1980s. The LBA estimated natural mortality for different periods of years, whereas the research model estimated additional mortality beyond a basic constant natural mortality during 1976-1993. In this report, we present only the research model that was fit to the data from 1975 to 2018.

## 2. Model Description

The original LBA model was described in detail by Zheng et al. (1995a, 1995b) and Zheng and Kruse (2002). The model combines multiple sources of survey, catch, and bycatch data using a maximum likelihood approach to estimate abundance, recruitment, selectivities, catches, and bycatch of the commercial pot fisheries and groundfish trawl fisheries. A full model description is provided in Appendix A. Francis' approaches for re-weighting the effective sample sizes for size composition data are detailed in Appendix C.
a-f. See appendix A.
g. Critical assumptions of the model:
i. The base natural mortality is constant over sex, shell condition and length and was estimated assuming a maximum age of 25 and applying the $1 \%$ rule (Zheng 2005).
ii. Survey and fisheries selectivities are a function of length and were constant over shell condition. Selectivities are also a function of sex except for trawl bycatch selectivities, which are the same for both sexes. Two different survey selectivities were estimated: (1) 1975-1981 and (2) 1982-2018, based on modifications to the trawl gear used in the assessment survey.
iii. Growth is a function of length and is assumed to not change over time for males. For females, growth-per-molt increments as a function of length were estimated for three periods (1975-1982, 1983-1993, and 1994-2018) based on sizes at maturity. Once mature, female red king crab grow with a much smaller growth increment per molt.
iv. Molting probabilities are an inverse logistic function of length for males. Females molt annually.
v. Annual fishing seasons for the directed fishery are short.
vi. The prior of survey catchability $(Q)$ was estimated to be 0.896 , based on a trawl experiment by Weinberg et al. (2004) with a standard deviation of 0.025 for some scenarios. $Q$ is assumed to be constant over time and is estimated in the model.
vii. Males mature at sizes $\geq 120 \mathrm{~mm}$ CL. For convenience, female abundance was summarized at sizes $\geq 90 \mathrm{~mm}$ CL as an index of mature females.
viii. Measurement errors were assumed to be normally distributed for length compositions and were log-normally distributed for biomasses.
h. Changes to the above since previous assessment: see Section A.3. Changes to the assessment methodology.
i. Outline of methods used to validate the code used to implement the model and whether the code is available: The code is available.

## 3. Model Selection and Evaluation

a. Alternative model configurations (scenarios):

2b: Scenario 2b is the same as scenario 2b in the SAFE draft report in September 2017 with correction of the two errors that result in overweighting small size length composition data of NMFS surveys and underweighting BSFRF survey biomass. This scenario assumes that BSFRF survey capture probabilities are 1.0 for all length groups. Under this assumption, NMFS survey selectivities are the products of crab availabilities (equal to BSFRF survey selectivities) and NMFS survey capture probabilities. A survey capture probability for a length group is simply defined as the proportion of the crab in the length group within the area-swept that is caught by the survey net. Also, groundfish fisheries bycatch is separated into trawl fisheries and fixed gear fisheries.

Scenario 2b includes:
(1) Base $M=0.18$, with an additional mortality level during 1980-1984 for males and two additional mortality levels (one for 1980-1984 and the other for 1976-1979 and 1985-1993) for females. Additional mortalities are estimated in the model.
(2) Including BSFRF survey data during 2007-2008 and 2013-2016. The BSFRF survey is treated as an independent survey, and no assumption is made about the capture probabilities of the BSFRF survey. In effect, survey selectivities for both surveys are estimated separately in the model.
(3) NMFS survey catchability is estimated in the model and is assumed to be constant over time. BSFRF survey catchability is assumed to be 1.0 .
(4) Two levels of molting probabilities for males: one before 1980 and one after 1979, based on survey shell condition data. Each level has two parameters.
(5) Estimating effective sample size from observed sample sizes. Stage-1 effective sample sizes are estimated as $\min (0.5 * \mathrm{n} 1, \mathrm{~N})$ for trawl surveys and $\min \left(0.1^{*} \mathrm{n} 1, \mathrm{~N}\right)$ for catch and bycatch, where n 1 is an observed sample size for a sex, N is the maximum sample size ( 200 for trawl surveys, 100 for males from the pot fishery and 50 for females from pot fishery and both males and females from the groundfish fisheries. There is a justification for enforcing a maximum limit to effective sample sizes because the number of length measurements is large (Fournier at al. 1998). The effective sample sizes are plotted against the implied effective sample sizes in Figures 6 and 7, where the implied effective sample sizes are estimated as follows:
$n_{y}=\sum_{l} \hat{P}_{y, l}\left(1-\hat{P}_{y, l}\right) / \sum_{l}\left(P_{y, l}-\hat{P}_{y, l}\right)^{2}$
where $\hat{P}_{y, l}$ and $P_{y, l}$ are estimated and observed size compositions in year $y$ and length group $l$, respectively.
(6) Standard survey data for males and NMFS survey retow data (during cold years) for females.
(7) Estimating initial year length compositions.

For scenario 2b, survey abundances $\hat{N}_{s, y, l}^{b}$ (BSFRF survey) and $\hat{N}_{s, y, l}^{n}$ (NMFS survey) by sex $s$ and in year $y$ and length group $l$ are computed as follows:

$$
\begin{align*}
& \hat{N}_{s, y, l}^{b}=N_{s, y, l} s_{s, l}^{b},  \tag{2}\\
& \hat{N}_{s, y, l}^{n}=N_{s, y, l} s_{s, l}^{n},
\end{align*}
$$

where $s_{s, l}^{b}$ and $s_{s, l}^{n}$ are survey selectivities for BSFRF and NMFS surveys by sex $s$ and in length group $l$, respectively, and $N_{s, y, l}$ is the population abundance by sex $s$ and in year y and length group $l$. BSFRF survey selectivities are computed as

$$
\begin{equation*}
s_{s, l}^{b}=\frac{1}{1+e^{-\beta_{s}^{b}\left(t-L_{50, s}^{b}\right)}} \tag{3}
\end{equation*}
$$

where $\beta$ and $L_{50}$ are parameters. Survey selectivity for the first length group ( 67.5 mm ) was assumed to be the same for both males and females, so only three parameters ( $\beta$, $L 50$ for females and $L 50$ for males) were estimated in the model for each survey. The BSFRF survey catchability is assumed to be 1.0.

Scenario 2b assumes that the BSFRF survey capture probabilities are 1.0 for all length groups. Under this assumption, NMFS survey selectivities are the products of crab availabilities (equal to BSFRF survey selectivities) and NMFS survey capture probabilities ( $p$ ):
$s_{s, l}^{n}=p_{s, l} s_{s, l}^{b}$.
Therefore, the model estimates NMFS survey capture probabilities and BSFRF survey selectivities and computes NMFS survey selectivities from these estimates. NMFS survey capture probabilities are computed as

$$
\begin{equation*}
p_{s, l}=\frac{Q}{1+e^{-\beta_{s}\left(t-L_{50, s}\right)}}, \tag{5}
\end{equation*}
$$

where $\beta$ and $L 50$ are parameters and similar to the survey selectivities, only three parameters ( $\beta, L 50$ for females and $L 50$ for males) were estimated in the model for each sex. $Q$ is the NMFS survey catchability and is estimated in the model with or without a prior from the double-bag experiment, depending on scenarios.

Since fishing times for both Tanner crab fishery and groundfish fishery are assumed to occur the same time, the fraction separation of fishing mortality rates for both fisheries is used to divide the total fishing mortality rate to individual fisheries, that is, $\mathrm{F}_{\mathrm{i}} / \mathrm{F}_{\text {tot }} *(1-$ $\left.\exp \left(-\mathrm{F}_{\text {tot }}\right)\right)$ for fishery i , and the sum of $\mathrm{F}_{\mathrm{i}}=\mathrm{F}_{\text {tot }}$.

2b-old: the scenario 2b in the SAFE report in September 2017 without two error corrections. The purpose to include this scenario is to compare it with scenario $2 b$ to examine the impacts of the two errors on the results.
18.0: renamed from scenario 2 bn 1 in May 2018 with some changes based on the requests of CPT and SSC and the same as scenario 2 b except with differences: (1) the total observer male biomass and total observer male length composition data in the directed pot fishery are used to replace discarded male biomass and discarded male length composition data, (2) total male selectivity and retained proportions in the directed pot fishery are used to replace retained selectivity and discarded male selectivity, and (3) due to high grading problems in some years since rationalization, two logistic curves are estimated for retained proportions: one before rationalization (before 2005) and another after 2004.
18.0a: the same as scenario 18.0 except with equal annual effective sample sizes of male and female length compositions. Annual effective sample sizes with scenario 18.0 may be different between male and female length composition data. To maintain the same level of effective sample sizes with scenario 18.0, stage-1 effective sample sizes for scenario 18.0a are estimated as $\min [0.25 * \mathrm{n}, \mathrm{N}]$ for trawl surveys and $\min (0.05 * \mathrm{n}, \mathrm{N})$ for catch and bycatch, where n is the sum of observed sample sizes for two sexes, N is the
maximum sample size ( 200 for trawl surveys, 100 for males from the pot fishery and 50 for females from pot fishery and both males and females from the groundfish fisheries.
18.0b: renamed from scenario 2 bn2 in May 2018 with some changes based on the requests of CPT and SSC and the same as scenario 18.0 except that only one logistic curve is estimated for all years for retained proportions and to deal with annual high gradings, annual adjusted factor parameter, $x_{t}$, is estimated for each year after 2004 and a logit transformation is used to make sure the adjusted factor, $u_{t}$, be $<1.0$ :
$u_{t}=\frac{e^{x_{t}}}{1+e^{x_{t}}}$
Annual retained proportions after 2004 are estimated as:
$S_{l, t}^{r e t}=u_{t} S_{l}^{r e t}$
To avoid overfitting the data, a negative likelihood value is computed as:
$\sum_{t}\left(u_{t}-1.0\right)^{2} /\left(2 \sigma^{2}\right)$
where $\sigma$ is the standard deviation of $u_{t}$ and is assumed to be 0.1 . The model results hardly change with either 0.1 or 0.2 .
18.0c: the same as scenario 18.0 except with the differences of total male selectivity and retained proportions in the directed pot fishery: (1) one logistic curve for total male selectivity is estimated with annual deviations of length at $50 \%$ selectivity parameter ( $\operatorname{dev} L_{50, t}^{\text {dir,tot }}$ ) and (2) another logistic curve is estimated for all years for retained proportions and for years after 2004 with annual deviations of length at $50 \%$ retained proportion parameter $\left(\operatorname{dev} L_{50, t}^{\text {ret }}\right.$ ). Similar to scenario 18.0b, after 2004, annual deviations are used to deal with annual high gradings.
To avoid overfitting the data, a negative likelihood value is computed as:
$0.1\left[\text { first difference }\left(\text { dev } L_{50, t}^{\text {dir,tot }}\right)\right]^{2}+0.1\left[\text { first difference }\left(\text { dev } L_{50, t}^{\text {ret }}\right)\right]^{2}$
b. Progression of results: See the new results at the beginning of the report.
c. Evidence of search for balance between realistic and simpler models: NA.
d. Convergence status/criteria: ADMB default convergence criteria.
e. Sample sizes for length composition data: observed sample sizes are summarized in Table 2, and estimated implied sample sizes and effective sample sizes are illustrated in Figures 6 and 7.
f. Credible parameter estimates: All estimated parameters seem to be credible.
g. Model selection criteria: The likelihood values were used to select among alternatives that could be legitimately compared by that criterion.
h. Residual analysis: Residual plots are illustrated in figures.
i. Model evaluation is provided under Results, below.
j. Jittering: the Stock Synthesis Approach is used to do jittering to find the optimum:

The Jitter factor of 0.1 is multiplied by a random normal deviation $r d e v=N(0,1)$, to a transformed parameter value based upon the predefined parameter:

$$
\begin{equation*}
\text { temp }=0.5 \text { rdev Jitter } \ln \left(\frac{P_{\max }-P_{\min }+0.0000002}{P_{v a l}-P_{\min }+0.0000001}-1\right), \tag{6}
\end{equation*}
$$

with the final jittered starting parameter value backtransformed as:

$$
\begin{equation*}
P_{\text {new }}=P_{\min }+\frac{P_{\max }-P_{\min }}{1.0+\exp (-2.0 \text { temp })}, \tag{7}
\end{equation*}
$$

where $P_{\max }$ and $P_{\text {min }}$ are upper and lower bounds of parameters and $P_{\text {val }}$ is the estimated parameter value before the jittering. Due to time constraints, the jittering approach is not used in this report.

## 4. Results

a. Effective sample sizes and weighting factors. Effective sample sizes and weighting factors. i. For scenario 18.0, effective sample sizes are illustrated in Figures 6 and 7.
ii. CVs are assumed to be 0.03 for retained catch biomass, and 0.07 for all bycatch biomasses, 0.53 for recruitment variation, and 0.23 for recruitment sex ratio.
iii. Initial trawl survey catchability $(Q)$ is estimated to be 0.896 with a standard deviation of 0.025 ( CV about 0.03 ) based on the double-bag experiment results. These values are used as a prior for estimating $Q$ in the model for all scenarios.
b. Tables of estimates.
i. Parameter estimates for scenarios 18.0 and 18.0 a are summarized in Tables 3-5.
ii. Abundance and biomass time series are provided in Table 6 for scenarios 18.0 and 18.0a.
iii. Recruitment time series for scenarios 18.0 and 18.0a are provided in Table 6.
iv. Time series of catch biomass is provided in Table 1.

Negative log-likelihood values and parameter estimates are summarized in Tables 4 and 5, respectively. Length-specific fishing mortality is equal to selectivity-at-length times the full fishing mortality. Estimated full pot fishing mortalities for females and full fishing mortalities for groundfish fisheries bycatch were very low due to low bycatch as well as handling mortality rates less than 1.0. Estimated recruits varied greatly from year to year (Table 6). Estimated selectivities for female pot bycatch were close to 1.0 for all mature females, and the estimated full fishing mortalities for female pot bycatch were lower than for male retained catch and bycatch (Table 5).
c. Graphs of estimates.
i. Selectivities and molting probabilities by length are provided in Figures 8 and 9 for scenarios 18.0, 18.0a, and 18.0c.

One of the most important results is estimated trawl survey selectivity (Figure 8). Survey selectivity affects not only the fitting of the data but also the absolute
abundance estimates. Estimated survey selectivities in Figure 8 are generally smaller than the capture probabilities in Figure A1 because survey selectivities include capture probabilities and crab availability. The NMFS survey catchability was estimated to be 0.896 from the trawl experiment. The reliability of estimated survey selectivities will greatly affect the application of the model to fisheries management. Under- or overestimates of survey selectivities will cause a systematic upward or downward bias of abundance estimates. Information about crab availability to the survey area at survey times will help estimate the survey selectivities.
For all scenarios, estimated molting probabilities during 1975-2018 (Figure 9) were generally lower than those estimated from the 1954-1961 and 1966-1969 tagging data (Balsiger 1974). Lower molting probabilities mean more oldshell crab, possibly due to changes in molting probabilities over time or shell aging errors. Overestimates or underestimates of oldshell crab will result in lower or higher estimates of male molting probabilities.
ii. Estimated total survey biomass and mature male and female abundances are plotted in Figure 10. Absolute mature male biomasses are illustrated in Figure 11.

Model estimated relative survey biomasses are very similar among the six scenarios and fit the survey data quite well. The absolute mature male biomass estimates are higher for scenarios $18.0,18.0 \mathrm{a}, 18.0 \mathrm{~b}$ and 18.0 c than for scenarios 2 b and 2 b -old in recent years. The model fits to BSFRF survey biomass are similar among six scenarios. The absolute mature male biomass estimates between scenarios 2 b and $2 \mathrm{~b}-$ old are very close: average relative error of $-1.6 \%$ and average absolute relative error of $7.5 \%$, and during the period covering the BSFRF survey data (2006-2017), relative errors ranging from $-10.4 \%$ to $6.4 \%$. Because of overweighting NMFS survey small length composition data and underweighting BSFRF survey biomass, scenario 2 b -old fits the NMFS survey data better than other scenarios. The two errors with scenario 2b-old do not affect past TACs and fishery.
Although the model did not fit the mature crab abundances directly, trends in the mature abundance estimates agree well with observed survey values except in 2014 and 2018 (Figure 10b). Estimated mature crab abundance increased dramatically in the mid 1970s then decreased precipitously in the early 1980s. Estimated mature crab abundance had increased during 1985-2009 with mature females being about 3 times more abundant in 2009 than in 1985 and mature males being about 2 times more abundant in 2009 than in 1985. Estimated mature abundance has declined since 2009 (Figure 10b). Model estimates of both male and female mature abundances have steadily declined since the late 2000s. Absolute mature male biomasses for all scenarios have a similar trend over time (Figure 11).
The fit to BSFRF survey data and estimated survey selectivities are illustrated in Figures 10c-e.
iii. Estimated recruitment time series are plotted in Figure 12 for scenarios 18.0 and 18.0a.
iv. Estimated fishing mortality rates are plotted against mature male biomass in Figure 13 for scenarios 18.0 and 18.0a.

The average of estimated male recruits from 1984 to 2017 (Figure 12) and mature male biomass per recruit were used to estimate $B_{35 \%}$. Alternative periods of 1976present and 1976-1983 were compared in our report. The full fishing mortalities for the directed pot fishery at the time of fishing were plotted against mature male biomass on Feb. 15 (Figure 13). Estimated fishing mortalities in most years before the current harvest strategy was adopted in 1996 were above $F_{35 \%}$ (Figure 13). Under the current harvest strategy, estimated fishing mortalities were at or above the $F_{35 \%}$ limits in 19981999, 2005-2009 for scenarios 18.0 and 18.0a but below the $F_{35 \%}$ limits in the other post-1995 years.

For scenario 18.0, estimated full pot fishing mortalities ranged from 0.00 to 2.41 during 1975-2017. Estimated values were greater than 0.40 during 1975-1982, 19841987, 1990-1991, 1993, 1998 and 2007-2008 (Table 5, Figure 13). For scenario 18.0a, estimated full pot fishing mortalities ranged from 0.00 to 2.36 during 1975-2017, with estimated values over 0.40 during 1975-1982, 1984-1987, 1990-1991, 1993, 1998, and 2007-2008 (Figure 13). Estimated fishing mortalities for pot female and groundfish fisheries bycatches were generally less than 0.06.
v. Estimated mature male biomass and recruitment are plotted to illustrate their relationships with scenario 18.0 (Figure 14a). Annual stock productivities are illustrated in Figure 14b.

Stock productivity (recruitment/mature male biomass) was generally lower during the last 20 years (Figure 14b).
Egg clutch data collected during summer surveys may provide information about mature female reproductive conditions. Although egg clutch data are subject to rating errors as well as sampling errors, data trends over time may be useful. Proportions of empty clutches for newshell mature females $>89 \mathrm{~mm}$ CL were high in some years before 1990, but have been low since 1990 (Figure 15). The highest proportion of empty clutches ( 0.2 ) was in 1986, and primarily involved soft shell females (shell condition 1). Clutch fullness fluctuated annually around average levels during two periods: before 1991 and after 1990 (Figure 15). The average clutch fullness was similar for these two periods (Figure 15). Egg clutch fullness during the last three years is relatively low.
d. Graphic evaluation of the fit to the data.
i. Observed vs. estimated catches are plotted in Figure 16.
ii. Model fits to total survey biomass are shown in Figure 10 with a standardized residual plot in Figure 17.
iii. Model fits to catch and survey proportions by length are illustrated in Figures 1824 and residual bubble plots are shown in Figures 25-26.

The model (six scenarios) fit the fishery biomass data well and the survey biomass reasonably well (Figures 10 and 16). Because the model estimates annual fishing mortality for directed pot male catch, undirected pot male bycatch, pot female bycatch, trawl and fixed gear bycatch, the deviations of observed and predicted (estimated) fishery biomass are mainly due to size composition differences.

The model also fit the length composition data well (Figures 18-24). The model also fit the length proportions of the total pot males well with different approaches (Figure 21).

Modal progressions are tracked well in the trawl survey data, particularly beginning in the mid-1990s (Figures 18 and 19). Cohorts first seen in the trawl survey data in 1975, 1986, 1990, 1995, 1999, 2002 and 2005 can be tracked over time. Some cohorts can be tracked over time in the pot bycatch as well (Figure 21), but the bycatch data did not track the cohorts as well as the survey data. Groundfish trawl bycatch data provide little information to track modal progression (Figures 23 and 24).
Standardized residuals of total survey biomass and proportions of length are plotted to examine their patterns. Residuals were calculated as observed minus predicted and standardized by the estimated standard deviation. Standardized residuals of total survey biomass did not show any consistent patterns (Figure 17). Standardized residuals of proportions of survey males appear to be random over length and year (Figure 25). There is an interesting pattern for residuals of proportions of survey females. Residuals were generally negative for large-sized mature females during 1975-1987 for scenarios 18.0 and 18.0a (Figure 26). Changes in growth over time or increased mortality may cause this pattern. The inadequacy of the model can be corrected by adding parameters to address these factors or with improved growth data.
e. Retrospective and historic analyses.

Two kinds of retrospective analyses were conducted for this report: (1) the 2018 model (scenario 18.0) hindcast results and (2) historical results. The 2018 model results are based on sequentially excluding one-year of data to evaluate the current model performance with fewer data. The historical results are the trajectories of biomass and abundance from previous assessments that capture both new data and changes in methodology over time. Treating the 2018 estimates as the baseline values, we can also evaluate how well the model had done in the past.
i. Retrospective analysis (retrospective bias in base model or models).

The performance of the 2018 model includes sequentially excluding one-year of data. The model with scenario 18.0 performed reasonably well during 2011-2017 with a lower terminal year estimates of mature male biomass in 2011-2013 and higher estimates in 2014-2016 (Figures 27-28).
ii. Historic analysis (plot of actual estimates from current and previous assessments).

The model first fit the data from 1985 to 2004 in the terminal year of 2004. Thus, sequentially incrementing the terminal year provided 10 historical assessments for comparison with the 2018 assessment model results (Figure 29). The main differences of the 2004 model were weighting factors and effective sample sizes for the likelihood functions. In 2004, the weighting factors were 1,000 for survey biomass, 2,000 for retained catch biomass and 200 for bycatch biomasses. The effective sample sizes were set to be 200 for all proportion data but weighting factors of 5,2 , and 1 were also respectively applied to retained catch proportions, survey proportions and bycatch proportions. Estimates of time series of abundance in 2004 were generally higher than those estimated after 2004 (Figure 29).

In 2005, to improve the fit for retained catch data, the weight for retained catch biomass was increased to 3,000 and the weight for retained catch proportions was increased to 6 . All other weights were not changed. In 2006, all weights were reconfigured. No weights were used for proportion data, and instead, effective sample sizes were set to 500 for retained catch, 200 for survey data, and 100 for bycatch data. Weights for biomasses were changed to 800 for retained catch, 300 for survey and 50 for bycatch. The weights in 2007 were the same as 2006. Generally, estimates of time series of abundance in 2005 were slightly lower than in 2006 and 2007, and there were few differences between estimates in 2006 and 2007 (Figure 29).
In 2008, estimated coefficients of variation for survey biomass were used to compute likelihood values as suggested by the CPT in 2007. Thus, weights were re-configured to: 500 for retained catch biomass, 50 for survey biomass, and 20 for bycatch biomasses. Effective sample size was lowered to 400 for the retained catch data. These changes were necessary for the estimation to converge and for a relatively good balanced fit to both biomasses and proportion data. Also, sizes at $50 \%$ selectivities for all fisheries data were allowed to change annually, subject to a random walk pattern, for all assessments before 2008. The 2008 model does not allow annual changes in any fishery selectivities. Except for higher estimates of abundance during the late 1980s and early 1990s, estimates of time series of abundance in 2008 were generally close to those in 2006 and 2007 (Figure 29).

During 2009-2013, the model was extended to the data through 1968. No weight factors were used for the NMFS survey biomass during 2009-2013 assessments. Since 2013, the model has fitted the data only back to 1975 for consistence of trawl survey data. Two levels of molting probabilities over time were used, shell conditions for males were combined, and length composition data of the BSFRF survey were used as well. In 2014 and 2015, the trawl survey time series were re-estimated and a trawl survey catchability was estimated for some scenarios.

Overall, both historical results (historic analysis) and the 2018 model results (retrospective analysis) performed reasonably well. No great overestimates or underestimates occurred as was observed in assessments for Pacific halibut (Hippoglossus stenolepis) (Parma 1993) and some eastern Bering Sea groundfish stocks (Zheng and Kruse 2002; Ianelli et al. 2003). Since the most recent model was not used to set TAC or overfishing limits until 2009, historical implications for management from the stock assessment errors cannot be evaluated at the current time. However, management implications of the ADF\&G stock assessment model were evaluated by Zheng and Kruse (2002).

Ratios of estimated retrospective recruitments to terminal estimates in 2018 as a function of number of years estimated in the model show converging to 1.0 as the number of years increase (Figure 28). Standard deviations of the ratios drop sharply from one year estimated in the model to two years (Figure 28), showing great uncertainty of recruitment estimates for terminal years. Based on these results, we suggest not using recruitment estimates in a terminal year for overfishing/overfished determination.
f. Uncertainty and sensitivity analyses
i. Estimated standard deviations of parameters are summarized in Table 5 for
scenarios 18.0 and 18.0a. Estimated standard deviations of mature male biomass are listed in Table 6.
ii. Probabilities for trawl survey catchability $Q$ are illustrated in Figure 30 for scenarios 18.0 and 18.0a using the mcmc approach; estimated $Q$ s are less than 1.0. Probabilities for mature male biomass and OFL in 2018 are illustrated in Figure 31 for scenarios 18.0 and 18.0a using the mcmc approach. The confidence intervals are quite narrow.
iii. Sensitivity analysis for handling mortality rate was reported in the SAFE report in May 2010. The baseline handling mortality rate for the directed pot fishery was set at 0.2 . A $50 \%$ reduction and $100 \%$ increase respectively resulted in 0.1 and 0.4 as alternatives. Overall, a higher handling mortality rate resulted in slightly higher estimates of mature abundance, and a lower rate resulted in a minor reduction of estimated mature abundance. Differences of estimated legal abundance and mature male biomass were small among these handling mortality rates.
iv. Sensitivity of weights. Sensitivity of weights was examined in the SAFE report in May 2010. Weights to biomasses (trawl survey biomass, retained catch biomass, and bycatch biomasses) were reduced to $50 \%$ or increased to $200 \%$ to examine their sensitivity to abundance estimates. Weights to the penalty terms (recruitment variation and sex ratio) were also reduced or increased. Overall, estimated biomasses were very close under different weights except during the mid-1970s. The variation of estimated biomasses in the mid-1970s was mainly caused by the changes in estimates of additional mortalities in the early 1980s.
g. Comparison of alternative model scenarios

These comparisons, based on the data through 2010, were reported in the SAFE report in May 2011. Estimating length proportions in the initial year (scenario 1a) results in a better fit of survey length compositions at an expense of 36 more parameters than scenario 1. Abundance and biomass estimates with scenario 1a are similar between scenarios. Using only standard survey data (scenario 1 b ) results in a poorer fit of survey length compositions and biomass than scenarios using both standard and re-tow data (scenarios $1,1 \mathrm{a}$, and 1c) and has the lowest likelihood value. Although the likelihood value is higher for using both standard survey and re-tow data for males (scenario 1) than using only standard survey for males (scenario 1c), estimated abundances and biomasses are almost identical. The higher likelihood value for scenario 1 over scenario 1 c is due to trawl bycatch length compositions.

In this report (September 2018), six scenarios are compared. Model estimated relative survey biomasses are very similar among the scenarios. The absolute mature male biomass estimates are higher for scenarios 18.0, 18.0a, 18.0b and 18.0c than for scenarios 2 b and 2 b -old during recent years. The model fits to BSFRF survey biomass are similar among six scenarios. The absolute mature male biomass estimates between scenarios 2 b and 2 b -old are very close: average relative error of $-1.6 \%$ and average absolute relative error of $7.5 \%$, and during the period covering the BSFRF survey data (2006-2017), relative errors ranging from $-10.4 \%$ to $6.4 \%$. Because of overweighting NMFS survey small length composition data and underweighting BSFRF survey biomass, scenario $2 b$-old fits the NMFS survey data better than other scenarios. The two errors with scenario 2 b -old do not affect past TACs and fishery.

We recommend scenario 18.0 or scenario 18.0a for overfishing determination for September 2018 because the results are hardly different among scenarios $18.0,18.0 \mathrm{a}, 18.0 \mathrm{~b}$ and 18.0 c and these two scenarios have the least number of estimated parameters. Scenario $2 b$ will be discontinued next year due to changes in data collection.

## F. Calculation of the OFL and ABC

1. Bristol Bay RKC is currently placed in Tier 3b (NPFMC 2007).
2. For Tier 3 stocks, estimated biological reference points include $B_{35 \%}$ and $F_{35 \%}$. Estimated model parameters were used to conduct mature male biomass-per-recruit analysis.
3. Specification of the OFL:

The Tier 3 can be expressed by the following control rule:
a) $\frac{B}{B^{*}}>1$
$F_{O F L}=F^{*}$
b) $\quad \beta<\frac{B}{B^{*}} \leq 1$
$F_{O F L}=F^{*}\left(\frac{B / B^{*}-\alpha}{1-\alpha}\right)$
c) $\frac{B}{B^{*}} \leq \beta$
directed fishery $F=0$ and $F_{O F L} \leq F^{*}$

Where
$B=$ a measure of the productive capacity of the stock such as spawning biomass or fertilized egg production. A proxy of $B, \mathrm{MMB}$ estimated at the time of primiparous female mating (February 15) is used as a default in the development of the control rule.
$F^{*}=F_{35 \%}$, a proxy of $F_{M S Y}$, which is a full selection instantaneous $F$ that will produce MSY at the MSY producing biomass,
$B^{*}=B_{35 \%}$, a proxy of $B_{M S Y}$, which is the value of biomass at the MSY producing level,
$\beta=$ a parameter with restriction that $0 \leq \beta<1$. A default value of 0.25 is used.
$\alpha=$ a parameter with restriction that $0 \leq \alpha \leq \beta$. A default value of 0.1 is used.
Because trawl bycatch fishing mortality is not related to pot fishing mortality, average trawl bycatch fishing mortality during 2008 to 2017 is used for the per recruit analysis as well as for projections in the next section. Pot female bycatch fishing mortality is set equal to pot male fishing mortality times 0.02, an intermediate level during 1990-2017. Some discards of legal males occurred since the IFQ fishery started in 2005, but the discard rates were much lower during 2007-2013 than in 2005 after the fishing industry minimized discards of legal males. However, due to the high proportion of large oldshell males, the discard rate increased greatly in 2014. The average of retained selectivities and discard male selectivities during 2016-2017 are used to represent current trends for per recruit analysis and projections. Average molting probabilities during 2008-2017 are used for per recruit analysis and projections.

Average recruitments during three periods are used to estimate $B_{35 \%}$ : 1976-2017, 1984-2017, and 1991-2017 (Figure 12). Estimated $B_{35 \%}$ is compared with historical mature male biomass in Figure 13a. We recommend using the average recruitment during 1984-present, corresponding to the 1976/77 regime shift. Note that recruitment period 1984-present has been used since 2011 to set the overfishing limits. Several factors support our recommendation. First, estimated recruitment was lower after 1983 than before 1984, which corresponded to brood years 1978 and later, after the 1976/77 regime shift. Second, high recruitments during the late 1960s and 1970s generally occurred when the spawning stock was primarily located in the southern Bristol Bay, whereas the current spawning stock is mainly in the middle of Bristol Bay. The current flows favor larvae hatched in the southern Bristol Bay (see the section on Ecosystem Considerations for SAFE reports in 2008 and 2009). Finally, stock productivity (recruitment/mature male biomass) was higher before the 1976/1977 regime shift.

If we believe that differences in productivity and other population characteristics before 1978 were caused by fishing, not by the regime shift, then we should use the recruitment from 19761983 (corresponding to brood years before 1978) as the baseline to estimate B35\%. If we believe that the regime shift during 1976/77 caused the productivity differences, then we should select the recruitments from period 1984-2018 as the baseline.

The control rule is used for stock status determination. If total catch exceeds OFL estimated at $B$, then "overfishing" occurs. If $B$ equals or declines below $0.5 B_{M S Y}$ (i.e., MSST), the stock is "overfished." If $B / B_{M S Y}$ or $B / B_{M S Y}$-proxy equals or declines below $\beta$, then the stock productivity is severely depleted and the fishery is closed.

The estimated probability distribution of MMB in 2018 is illustrated in Figure 30. Based SSC suggestion in 2011, $\mathrm{ABC}=0.9^{*} \mathrm{OFL}$. However, the CPT recommended $\mathrm{ABC}=0.8^{*} \mathrm{OFL}$ in May 2018, which is used to estimate ABC in this report.

Status and catch specifications ( $1,000 \mathrm{t}$ ) (scenario 18.0a):

| Year | MSST | Biomass <br> $($ MMB $)$ | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | $13.03^{\mathrm{A}}$ | $27.25^{\mathrm{A}}$ | 4.49 | 4.54 | 5.41 | 6.82 | 6.14 |
| $2015 / 16$ | $12.89^{\mathrm{B}}$ | $27.68^{\mathrm{B}}$ | 4.52 | 4.61 | 5.31 | 6.73 | 6.06 |
| $2016 / 17$ | $12.53^{\mathrm{C}}$ | $25.81^{\mathrm{C}}$ | 3.84 | 3.92 | 4.35 | 6.64 | 5.97 |
| $2017 / 18$ | $12.74^{\mathrm{D}}$ | $24.86^{\mathrm{D}}$ | 2.99 | 3.09 | 3.48 | 5.60 | 5.04 |
| $2018 / 19$ |  | $20.80^{\mathrm{D}}$ |  |  |  | 5.34 | 4.27 |

The stock was above MSST in 2017/18 and hence was not overfished. Overfishing did not occur.

Status and catch specifications (million lbs):

| Year | MSST | Biomass <br> $($ MMB | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | ---: | :---: | ---: | :---: |
| $2014 / 15$ | $28.7^{\mathrm{A}}$ | $60.1^{\mathrm{A}}$ | 9.99 | 10.01 | 11.92 | 15.04 | 13.53 |
| $2015 / 16$ | $28.4^{\mathrm{B}}$ | $61.0^{\mathrm{B}}$ | 9.97 | 10.17 | 11.71 | 14.84 | 13.36 |
| $2016 / 17$ | $27.6^{\mathrm{C}}$ | $56.9^{\mathrm{C}}$ | 8.47 | 8.65 | 9.59 | 14.63 | 13.17 |
| $2017 / 18$ | $28.1^{\mathrm{D}}$ | $54.8^{\mathrm{D}}$ | 6.60 | 6.82 | 7.67 | 12.35 | 11.11 |
| $2018 / 19$ |  | $45.9^{\mathrm{D}}$ |  |  |  | 11.76 | 9.41 |

Notes:
A - Calculated from the assessment reviewed by the Crab Plan Team in September 2015
B - Calculated from the assessment reviewed by the Crab Plan Team in September 2016
C - Calculated from the assessment reviewed by the Crab Plan Team in September 2017
D - Calculated from the assessment reviewed by the Crab Plan Team in September 2018
4. Based on the $B_{35 \%}$ estimated from the average male recruitment during 1984-2017, the biological reference points and OFL are illustrated in Table 4.
5. Based on the CPT recommendation of $20 \%$ buffer rule in May 2018, $\mathrm{ABC}=0.8 * \mathrm{OFL}$ (Table 4). If $\mathrm{P}^{*}=49 \%$ is used, the ABC will be higher.

## G. Rebuilding Analyses

NA.

## H. Data Gaps and Research Priorities

1. The following data gaps exist for this stock:
a. Information about changes in natural mortality in the early 1980s;
b. Un-observed trawl bycatch in the early 1980s;
c. Natural mortality;
d. Crab availability to the trawl surveys;
e. Juvenile crab abundance;
f. Female growth per molt as a function of size and maturity;
g. Changes in male molting probability over time.
2. Research priorities:
a. Estimating natural mortality;
b. Estimating crab availability to the trawl surveys;
c. Surveying juvenile crab abundance in nearshore;
d. Studying environmental factors that affect the survival rates from larvae to recruitment.

## I. Projections and Future Outlook

## 1. Projections

Future population projections primarily depend on future recruitment, but crab recruitment is difficult to predict. Therefore, annual recruitment for the projections is a random selection from estimated recruitments during 1984-2018. Besides recruitment, the other major uncertainty for the projections is estimated abundance in 2018 . The 2018 abundance is randomly selected from the estimated normal distribution of the assessment model output for each replicate. Three scenarios of fishing mortality for the directed pot fishery are used in the projections:
(1) No directed fishery. This was used as a base projection.
(2) $F_{40 \%}$. This fishing mortality creates a buffer between the limits and target levels.
(3) $F_{35 \%}$. This is the maximum fishing mortality allowed under the current overfishing definitions.

Each scenario is replicated 1,000 times and projections made over 10 years beginning in 2018 (Table 7).

As expected, projected mature male biomasses are much higher without the directed fishing mortality than under the other scenarios. At the end of 10 years, projected mature male biomass is above $B_{35 \%}$ for all scenarios (Table 7; Figure 32). Projected retained catch for the $F_{35 \%}$ scenario is higher than those for the $F_{40 \%}$ scenario (Table 7, Figure 33). Due to the poor recruitment in recent years, the projected biomass and retained catch are expected to decline during the next few years.

## 2. Near Future Outlook

The near future outlook for the Bristol Bay RKC stock is a declining trend. The three recent aboveaverage year classes (hatching years 1990, 1994, and 1997) had entered the legal population by 2006 (Figure 34). Most individuals from the 1997 year class will continue to gain weight to offset loss of the legal biomass to fishing and natural mortalities. The above-average year class (hatching year 2000) with lengths centered around 87.5 mm CL for both males and females in 2006 and with lengths centered around $112.5-117.5 \mathrm{~mm}$ CL for males and around 107.5 mm CL for females in 2008 has largely entered the mature male population in 2009 and the legal population by 2014 (Figure 34). No strong cohorts have been observed in the survey data after this cohort through 2010 (Figure 34). There was a huge tow of juvenile crab of size $45-55 \mathrm{~mm}$ in 2011, but these juveniles were not tracked during 2012-2018 surveys. This single tow is unlikely to be an indicator for a strong cohort. The high survey abundance of large males and mature females in 2014 cannot be explained by the survey data during the previous years and were also inconsistent with the 2015-2018 survey results (Figure 34). Due to lack of recruitment, mature and legal crab should continue to decline next year. Current crab abundance is still low relative to the late 1970s, and without favorable environmental conditions, recovery to the high levels of the late 1970s is unlikely.

Table 5(18.0a). Summary of estimated model parameter values and standard deviations and limits for scenario 18.0a for Bristol Bay red king crab. All values are on a $\log$ scale. Male recruit in year $t$ is $\exp \left(\right.$ mean $\left.^{\text {males }}{ }_{t}\right)$, and female recruit in year $t$ is $\left.\exp \left(\text { mean }+ \text { males }_{t}+\text { females }\right)_{t}\right)$.

Table 6(18.0). Annual abundance estimates (million crab), mature male biomass (MMB, 1000 t ), and total survey biomass ( 1000 t ) for red king crab in Bristol Bay estimated by length-based analysis (scenario 18.0) from 1975-2018. Mature male biomass for year $t$ is on Feb. 15, year $t+1$. Size measurements are mm carapace length.

Table 6(18.0a). Annual abundance estimates (million crab), mature male biomass (MMB, 1000 t ), and total survey biomass ( 1000 t ) for red king crab in Bristol Bay estimated by length-based analysis (scenario 18.0a) from 1975-2018. Mature male biomass for year $t$ is on Feb. 15, year $t+1$. Size measurements are mm carapace length.

| Year (t) | Males |  |  |  | Females | Total Recruits | Total Survey Biomass |  |

Table 7(18.0). Comparison of projected mature male biomass (1000 t) on Feb. 15, retained catch (1000 t), their $95 \%$ limits, and mean fishing mortality with no directed fishery, $\mathrm{F}_{40 \%}$, and $\mathrm{F}_{35 \%}$ harvest strategy with $\mathrm{F}_{35 \%}$ constraint during 2018-2027. Parameter estimates with scenario 18.0 are used for the projection.

Figure 1. Current harvest rate strategy (line) for the Bristol Bay red king crab fishery and annual prohibited species catch (PSC) limits (numbers of crab) of Bristol Bay red king crab in the groundfish fisheries in zone 1 in the eastern Bering Sea. Harvest rates are based on current-year estimates of effective spawning biomass (ESB), whereas PSC limits apply to previous-year ESB.

Data by type and year

Figure 2. Data types and ranges used for the stock assessment.

Figure 3. Retained catch biomass and bycatch mortality biomass ( $t$ ) for Bristol Bay red king crab from 1953 to 2017. Handling mortality rates were assumed to be 0.2 for the directed pot fishery, 0.25 for the Tanner crab fishery, 0.8 for the trawl fisheries, and $50 \%$ for the fixed gear fisheries.

Figure 4. Comparison of survey legal male abundances and catches per unit effort for Bristol Bay red king crab from 1968 to 2017.

Figure 5a. Survey abundances by 5-mm carapace length bin for male Bristol Bay red king crab from 1968 to 2018.

Figure 5b. Survey abundances by 5 mm carapace length bin for female Bristol Bay red king crab from 1968 to 2018 .

Figure 6. Relationship between implied effective sample sizes (section 3(a)(5)(i)) and effective sample sizes (see effective sample sizes for scenario 18.0) for length/sex composition data with scenario 18.0: trawl survey data.

Figure 7. Relationship between implied effective sample sizes (section 3(a)(5)(i)) and effective sample sizes (see effective sample sizes for scenario 18.0) for length/sex composition data with scenario 18.0: directed pot fishery data.

Figure $8 \mathrm{a}(18.0)$. Estimated trawl survey selectivities under scenario 18.0. Pot, Tanner crab, fixed gear and trawl handling mortality rates were assumed to be $0.2,0.25,0.5$ and 0.8 , respectively.

Figure 8a(18.0a). Estimated trawl survey selectivities under scenario 18.0a. Pot, Tanner crab, fixed gear and trawl handling mortality rates were assumed to be $0.2,0.25,0.5$ and 0.8 , respectively.

Figure 8b. Comparisons of estimated NMFS trawl survey selectivities for period 1982-2018 under scenarios 18.0, 18.0a, and 18.0c. Pot, Tanner crab, fixed gear and trawl handling mortality rates were assumed to be $0.2,0.25,0.5$ and 0.8 , respectively.

Figure 8c. Estimated pot fishery selectivities and groundfish trawl bycatch selectivities under scenario 18.0. Pot, Tanner crab, fixed gear and trawl handling mortality rates were assumed to be $0.2,0.25,0.5$ and 0.8 , respectively.

Figure 9(18.0). Comparison of estimated probabilities of molting of male red king crab in Bristol Bay for different periods. Molting probabilities for periods 1954-1961 and 1966-1969 were estimated by Balsiger (1974) from tagging data. Molting probabilities for 1975-2018 were estimated with a length-based model.

Figure 10a. Comparisons of area-swept estimates of total survey biomass and model prediction for model estimates in 2018 under scenarios 18.0, 18.0a, 8.0b, 18.0c, 2b and 2b-old. Pot, Tanner crab, fixed gear and trawl handling mortality rates were assumed to be $0.2,0.25,0.5$ and 0.8 , respectively. The error bars are plus and minus 2 standard deviations.

Figure 10b. Comparisons of area-swept estimates of male ( $>119 \mathrm{~mm}$ ) and female ( $>89 \mathrm{~mm}$ ) abundance and model prediction for model estimates in 2018 under scenarios 18.0, 18.0a, and 18.0 c . Pot, Tanner crab, fixed gear and trawl handling mortality rates were assumed to be $0.2,0.25$, 0.5 and 0.8 , respectively.

Figure 10c. Comparisons of total survey biomass estimates by the BSFRF survey and the model for model estimates in 2018 (scenarios 18.0, 18.0a, 8.0b, 18.0c, 2 b and 2 b -old). The error bars are plus and minus 2 standard deviations of scenario 18.0.

Figure 10d. Comparisons of estimated BSFRF survey selectivities with scenarios 18.0, 18.0a, and 18.0 c . The catchability is assumed to be 1.0 .

Figure $10 \mathrm{e}(18.0,18.0 \mathrm{a}, \& 18.0 \mathrm{c})$. Comparisons of length compositions by the BSFRF survey and the model estimates during 2007-2008 and 2013-2016 with scenarios 18.0 (solid black), 18.0a (dashed red), and 18.0c (green lines).

Appendix A. Description of the Bristol Bay Red King Crab Model

## a. Model Description

## i. Population model

The original LBA model was described in detail by Zheng et al. (1995a, 1995b) and Zheng and Kruse (2002). Crab abundances by carapace length and shell condition in any one year are modeled to result from abundances in the previous year minus catch and handling and natural mortalities, plus recruitment, and additions to or losses from each length class due to growth:
$N_{l, t+1}^{s}=\sum_{l^{\prime}=1}^{l}\left\{P_{l^{\prime}, l, t}^{s}\left[\left(N_{l^{\prime}, t}^{s}+O_{l^{\prime}, t}^{s}\right) e^{-M_{i}^{s}}-\left(C_{l^{\prime}, t}^{s}+D_{l^{\prime}, t}^{s}\right) e^{\left(y_{t}-1\right) M_{t}^{s}}-T_{l^{\prime}, t}^{s} e^{\left(j_{t}-1\right) M_{i}^{s}}\right] m_{l^{\prime}, t}^{s}\right\}+R_{t+1}^{s} U_{l}^{s}$
$O_{l, t+1}^{s}=\left[\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-M_{t}^{s}}-\left(C_{l, t}^{s}+D_{l, t}^{s}\right) e^{\left(y_{t}-1\right) M_{t}^{s}}-T_{l, t}^{s} e^{\left(j_{t}-1\right) M_{t}^{s}}\right]\left(1-m_{l, t}^{s}\right)$
where $N_{l, t}^{s}$ is the number of new shell crab of sex $s$ in length-class $l$ at the start of year $t, O_{l, t}^{s}$ the number of old shell crab of sex $s$ in length-class $l$ at the start of year $t, P_{l, l, s}^{s}$ the proportion during year $t$ of an animals of sex $s$ in length-class $l$ ' which grow into length-class $l$ given that they moulted, $M_{t}^{s}$ the rate of natural mortality on animals of sex $s$ during year $t, m_{l, t}^{s}$ the probability that an animal of $\operatorname{sex} s$ in length-class $l$ will moult during year $t, R_{t+1}^{s}$ the recruitment [to the model] of animals of sex $s$ during year $t, U_{l}^{s}$ the proportion of recruits of sex $s$ which recruit to length-class $l, C_{l, t}^{s}$ the retained catch (in numbers) of animals of sex $s$ in length-class $l$ during year $t, D_{l, t}^{s}$ the discarded catch of animals of sex $s$ in length-class $l$ during year $t$ in the directed fishery, $T_{l, t}^{s}$ the discarded catch of animals of sex $s$ in length-class $l$ during year $t$ in the Tanner crab fishery and the groundfish fisheries, $y_{t}$ the time in years between survey and the directed pot fishery during year $t$, and $j_{t}$ the time in years between survey and the Tanner and groundfish fisheries during year $t$.
The minimum carapace length for both males and females is set at 65 mm , and crab abundance is modeled with a length-class interval of 5 mm . The last length class includes all crab $\geq 160-\mathrm{mm}$ CL for males and $\geq 140-\mathrm{mm}$ CL for females. Thus, length classes/groups are 20 for males and 16 for females. Since females moult annually (Powell 1967), females have only the first part of the equation (A1).
The growth increment is assumed to be gamma distributed with mean which depends linearly on pre-moult length, i.e.:
$P_{l, l, t}^{s}=\int_{L_{l}-\Delta L / 2}^{L_{l}+\Delta L / 2} \frac{x^{\alpha_{L /, t}^{s}} e^{x / \beta^{s}}}{\left(\beta^{s}\right)^{\alpha_{L /, x}^{s}} \Gamma\left(\alpha_{L_{l}, t}^{s}\right)} d x \quad \alpha_{L_{L}, t}^{s} \beta^{s}=a_{t}^{s}+b_{t}^{s} L_{l}$
where $L_{l}$ is the mid-point of length-class $l, \Delta L$ the width of each size-class ( 5 mm carapace length), $a_{t}^{s}, b_{t}^{s}$ the parameters of the length-growth increment relationship for sex $s$ and year $t$, and $\beta^{s}$ the parameter determining the variance of the growth increment. Growth is time-invariant for males, and specified for three time-blocks for females (1968-82; 1983-93; 1994-2017) based on
changes to the size at maturity for females. The probability of moulting as a function of length for males is given by an inverse logistic function, i.e.:

$$
\begin{equation*}
m_{l}=\frac{1}{1+e^{\tilde{\beta}\left(L_{l}-L_{50}\right)}} \tag{A3}
\end{equation*}
$$

where $\tilde{\beta}, L_{50}$ are the parameters which determine the relationship between length and the probability of moulting.
Recruitment is defined as recruitment to the model and survey gear rather than recruitment to the fishery. Recruitment is separated into a time-dependent variable, $R_{t+1}^{s}$, and size-dependent variables, $U_{l}^{s}$, representing the proportion of recruits belonging to each length class. $R_{t+1}^{s}$ is assumed to consist of crab at the recruiting age with different lengths and thus represents year class strength for year $t$. The proportion of recruits by length-class, $U_{l}^{s}$, is described using a gamma distribution with parameters $\alpha_{l}^{s}$ and $\beta_{l}^{s}$. Because of different growth rates, recruitment is estimated separately for males and females under a constraint of approximately equal sex ratios of recruitment over time.

## ii. Catches and Fisheries Selectivities

Before 1990, no observed bycatch data were available in the directed pot fishery; the crab that were discarded and died in those years were estimated as the product of handling mortality rate, legal harvest rates, and mean length-specific selectivities. It is difficult to estimate bycatch from the Tanner crab fishery before 1991. A reasonable index to estimate bycatch fishing mortalities is potlifts of the Tanner crab fishery within the distribution area of Bristol Bay red king crab. Thus, bycatch fishing mortalities from the Tanner crab fishery before 1991 were estimated to be proportional to the smoothing average of potlifts east of $163^{\circ} \mathrm{W}$. The smoothing average is equal to $\left(P_{t-2}+2 P_{t-1}+3 P_{t}\right) / 6$ for the potlifts in year t . The smoothing process not only smoothes the annual number of potlifts, it also indexes the effects of lost pots during the previous years. All bycatches are death catches because the model fits the estimated observed death bycatches.
The catch (by sex) in numbers by the directed fishery is:

$$
\begin{equation*}
G_{l, t}^{s}=\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-y_{t} M_{t}^{s}}\left(1-e^{-F_{l, t}^{s}}\right) \tag{A4}
\end{equation*}
$$

where $F_{l, t}^{s}$ is the fishing mortality rate during year $t$ on animals of sex $s$ in length-class $l$ due to the directed fishery:
$F_{l, t}^{s}= \begin{cases}{\left[\left(S_{l}^{\text {dir,land }}\left(1+h_{t} \phi\right)+S_{l}^{\text {dir,disc,mal }}\right] F_{t}^{\text {dir }}\right.} & \text { if } s=\mathrm{mal} \\ S_{l}^{\text {dir,disc, }{ }^{\text {fem }}} F_{t}^{\text {disc,fem }} & \text { if } s=\text { fem }\end{cases}$
$F_{l, t}^{s}=\left\{\begin{array}{lr}{\left[S_{l}^{\text {dir,land }}\left(1+h_{t} \emptyset\right)+S_{l}^{\text {dir,disc,mal }}\right] F_{t}^{\text {dir }}} & \text { if } s=\text { mal and scen. } 2 b \\ {\left[S_{l}^{\text {tot,mal }} S_{l, t}^{r e t}+S_{l}^{\text {tot,mal }}\left(1-S_{l, t}^{r e t}\right) \emptyset\right] F_{t}^{\text {dir }}} & \text { if s is male and other scen } . \\ S_{l}^{\text {dir,disc,fem }} F_{t}^{\text {disc,fem }} & \text { if } s=\text { fem }\end{array}\right.$
where $S_{l}^{\text {dir,land }}$ is the selectivity pattern for the landings by the directed fishery, $S_{l}^{\text {dir,disc,s }}$ the selectivity pattern for the discards in the directed fishery by sex, $S_{l}^{\text {tot,mal }}$ the total male selectivity in the directed fishery, $S_{l, t}^{r e t}$ the retained proportions of males in the directed fishery, $F_{t}^{\text {dir }}$ the fullyselected fishing mortality during year $t$ (on males), $F_{t}^{\text {disc,fem }}$ the fully-selected fishing mortality on female animals during year $t$ related to discards in the directed fishery, $\phi$ the handling mortality (the proportion of animals which die due to being returned to the water following capture), and $h_{t}$ the rate of high-grading during year $t$, i.e. discards of animals which can be legally-retained by the directed pot fishery (non-zero only for 2005-2016).
There are no landings of females in a male-only fishery, while the landings $C$ of males in the directed fishery and discards $D$ of males in the directed fishery are:

$$
\begin{align*}
& C_{l, t}^{\mathrm{mal}}=\left(N_{l, t}^{\mathrm{mal}}+O_{l, t}^{\mathrm{mal}}\right) e^{-y_{l} M_{t}^{\mathrm{mal}}}\left(1-e^{-S_{l}^{\text {dirl.and }} F_{t}^{\text {dir }}}\right)  \tag{A6}\\
& D_{l, t}^{\mathrm{mal}}=G_{l, t}^{\text {mal }}-C_{l, t}^{\mathrm{mal}}
\end{align*}
$$

The catch (by sex) in numbers by the Tanner crab and groundfish fisheries in length-class $l$ during year $t$ is given by:

$$
\begin{equation*}
T_{l, t}^{s}=\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-j_{t} M_{t}^{s}} e^{-F_{l, t}^{s}}\left(1-e^{-\tilde{F}_{l, t}^{s}}\right) \tag{A7}
\end{equation*}
$$

where $\tilde{F}_{l, t}^{s}$ is the fishing mortality rate during year $t$ on animals of sex $s$ in length-class $l$ due to the Tanner crab and groundfish fisheries:
$\widetilde{F}_{l, t}^{s}=S_{l}^{\text {Tanner,s }} F_{t}^{\text {Tanner,s }}+S_{l}^{\text {trawl }} F_{t}^{\text {trawl }}+S_{l}^{f i x} F_{t}^{f i x}$
where $S_{l}^{\text {Taner, } s}$ is the selectivity pattern for the discards in the Tanner crab fishery by sex, $F_{t}^{\text {Tanner,s }}$ the fully-selected fishing mortality during year $t$ on animals of sex $s$ during year $t$ due to this fishery, $S_{l}^{\text {trawl }}$ the selectivity pattern for the bycatch in the groundfish trawl fishery, $F_{t}^{\text {trawl }}$ the fullyselected fishing mortality due to the groundfish trawl fishery, $S_{l}^{f i x}$ the selectivity pattern for the bycatch in the groundfish fixed gear fishery, and $F_{t}^{f i x}$ the fully-selected fishing mortality due to the groundfish fixed gear fishery.

The bycatches by sex are estimated from the Tanner crab fishery, $T C_{l, t}^{s}$, groundfish trawl fishery, $G T_{l, t}^{s}$, and groundfish fixed gear fishery, $G F_{l, t}^{s}$, as follow:

$$
\begin{align*}
& T C_{l, t}^{s}=\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-j_{t} M_{t}^{s}} e^{-F_{l, t}^{s}}\left(1-e^{-\tilde{F}_{l, t}^{s}}\right) S_{l}^{\text {Tanner,s } s} F_{t}^{\text {Tanner,s } s} / \tilde{F}_{l, t}^{s} \\
& G T_{l, t}^{s}=\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-j_{t} M_{t}^{s}} e^{-F_{l, t}^{s}}\left(1-e^{-\tilde{F}_{l, t}^{s}}\right) S_{l}^{\text {trawl }} F_{t}^{\text {trawl }} / \tilde{F}_{l, t}^{s}  \tag{A9}\\
& G F_{l, t}^{s}=\left(N_{l, t}^{s}+O_{l, t}^{s}\right) e^{-j_{l} M_{t}^{s}} e^{-F_{l, t}^{s}}\left(1-e^{-\tilde{F}_{l, t}^{s}}\right) S_{l}^{\text {fixed }} F_{t}^{\text {fixed }} / \widetilde{F}_{l, t}^{s}
\end{align*}
$$

For scenarios separating mature and immature crab, discarded female bycatch in numbers is separated into immature and mature bycatches. The female bycatches in the directed fishery in length-class $l$ and during year $t, D_{l, t}^{i}$ and $D_{l, t}^{m}$, and $T_{l, t}^{i}$ and $T_{l, t}^{m}$, are:
$D_{l, t}^{i}=N_{l, t}^{i} e^{-y_{t} M_{t}^{f e m}}\left(1-e^{-F_{l, t}^{f m}}\right)$
$D_{l, t}^{m}=N_{l, t}^{m} e^{-y_{t} M_{i}^{f e m}}\left(1-e^{-F_{l, t}^{f e m}}\right)$
The female bycatches (by maturity) in numbers by the Tanner crab and groundfish fisheries in length-class $l$ during year $t$ for scenario 2 are given by:
$T_{l, t}^{i}=N_{l, t}^{i} e^{-j_{t} M_{i}^{f e m}} e^{-F_{l, t}^{f e m}}\left(1-e^{-\tilde{F}_{l, t}^{\ell m}}\right)$
$T_{l, t}^{m}=N_{l, t}^{m} e^{-j_{t} M_{t}^{f e m}} e^{-F_{l, t}^{f e m}}\left(1-e^{-\tilde{F}_{l, t}^{\text {sem }}}\right)$
Retained selectivity, $S^{\text {dir,land }}$, selectivity for females in the directed fishery, $S^{\text {dir,dis,fem }}$, total male selectivity, $S_{l}^{\text {tot,mal }}$, retained proportions, $S_{l, t}^{r e t}$, selectivities for males and females in the groundfish trawl and fixed gear fisheries, $S^{\text {trawl }}$ and $S^{f i x}$, and selectivity for males and females in the Tanner crab fishery, $S^{\text {Tanner,s }}$, are all assumed to be logistic functions of length:

$$
\begin{equation*}
S_{l}^{\text {type }}=\frac{1}{1+e^{-\beta^{\text {type }}\left(t-L_{50}^{\text {tppe }}\right)}} \tag{A12}
\end{equation*}
$$

Different sets of parameters $\left(\beta, L_{50}\right)$ are estimated for retained males, female pot bycatch, male and female trawl bycatch, and discarded males and females from the Tanner crab fishery.

For scenario 2 b , male pot bycatch selectivity in the directed fishery is modeled by two linear functions:

$$
\begin{align*}
& s_{l}=\varphi+\kappa l, \quad \text { if } t<135 \mathrm{~mm} \mathrm{CL} \\
& s_{l}=s_{l-1}+5 \gamma, \quad \text { if } l>134 \mathrm{~mm} \mathrm{CL} \tag{A13}
\end{align*}
$$

where $\varphi, \kappa, \gamma$ are parameters.

## iii. Trawl Survey Selectivities

Trawl survey selectivities are estimated as

$$
\begin{equation*}
S_{l, t}^{s}=\frac{Q}{1+e^{-\beta_{t}^{s}\left(t-L_{50, t}^{s}\right)}} \tag{A14}
\end{equation*}
$$

with different sets of parameters ( $\beta, L_{50}$ ) estimated for males and females as well as two different periods (1975-81 and 1982-17). Survey selectivity for the first length group ( 67.5 mm ) was assumed to be the same for both males and females, so only three parameters ( $\beta, L_{50}$ for females and $L_{50}$ for males) were estimated in the model for each of the four periods. Parameter $Q$ was called the survey catchability that was estimated based on a trawl experiment by Weinberg et al. (2004; Figure A1). $Q$ was assumed to be constant over time.

Assuming that the BSFRF survey caught all crab within the area-swept, the ratio between NMFS abundance and BSFRF abundance is a capture probability for the NMFS survey net. The Delta method was used to estimate the variance for the capture probability. A maximum likelihood method was used to estimate parameters for a logistic function as an estimated capture probability
curve (Figure A1). For a given size, the estimated capture probability is smaller based on the BSFRF survey than from the trawl experiment, but the $Q$ value is similar between the trawl experiment and the BSFRF surveys (Figure A1). Because many small-sized crab are likely in the shallow water areas that are not accessible for the trawl survey, NMFS trawl survey selectivity consists of capture probability and crab availability.

## iv. Estimating Bycatch Fishing Mortalities for Years without Observer Data

Observer data are not available for the directed pot fishery before 1990 and the Tanner crab fishery before 1991. There are also extremely low observed bycatches in the Tanner crab fishery during 1994 and 2006-2009. Bycatch fishing mortalities for male and females during 1975-1989 in the directed pot fishery were estimated as

$$
\begin{equation*}
F_{t}^{d i s c, s}=r^{s} F_{t}^{d i r} \tag{A15}
\end{equation*}
$$

where $r^{s}$ is the median ratio of estimated bycatch discard fishing mortalities to the estimated directed pot fishing mortalities during 1990-2004 for sex $s$. Directed pot fishing practice has changed after 2004 due to fishery rationalization.

We used pot fishing effort (potlifts) east of $163^{\circ} \mathrm{W}$ in the Tanner crab fishery to estimate red king crab bycatch discard fishing mortalities in that fishery when observer data are not available (19751990, 1994, 2006-2009):
$F_{t}^{\text {Tanner,s }}=a^{s} E_{t}$
where $a^{s}$ is the mean ratio of estimated Tanner crab fishery bycatch fishing mortalities to fishing efforts during 1991-1993 for sex s, and $E_{t}$ is Tanner crab fishery fishing efforts east of $163^{\circ} \mathrm{W}$ in year $t$. Due to fishery rationalization after 2004, we used the data only during 1991-1993 to estimate the ratio.
b. Software Used: AD Model Builder (Fournier et al. 2012).

## c. Likelihood Components

A maximum likelihood approach was used to estimate parameters. For length compositions ( $p_{l, t, s, s h}$ ), the likelihood functions are :

$$
\begin{align*}
& R f=\prod_{l=1}^{L} \prod_{t=1}^{T} \prod_{s=1}^{2} \prod_{s h=1}^{2} \frac{\left\{\exp \left[-\frac{\left(p_{l, t, s, s h}-\hat{p}_{l, t, s, s h}\right)^{2}}{2 \sigma^{2}}\right]+0.01\right\}}{\sqrt{2 \pi \sigma^{2}}}  \tag{A17}\\
& \sigma^{2}=\left[\hat{p}_{l, t, s, s h}\left(1-\hat{p}_{l, t, s, s h}\right)+0.1 / L\right] / n
\end{align*}
$$

where $L$ is the number of length groups, $T$ the number of years, and $n$ the effective sample size, which was estimated for trawl survey and pot retained catch and bycatch length composition data from the directed pot fishery, and was assumed to be 50 for groundfish trawl and Tanner crab fisheries bycatch length composition data.

The weighted negative log likelihood functions are:

Length compositions: $-\sum \ln \left(R f_{i}\right)$
Biomasses otherthan survey: $\lambda_{j} \sum\left[\ln \left(C_{t} / \hat{C}_{t}\right)^{2}\right]$
NMFS surveybiomass: $\sum\left[\ln \left(B_{t} / \hat{B}_{t}\right)^{2} /\left(2 \ln \left(C V_{t}^{2}+1\right)\right)\right]$
BSFRF mature males: $\quad \sum\left[\ln \left(\ln \left(C V_{t}^{2}+1\right)\right)^{0.5}+\ln \left(B_{t} / \hat{B}_{t}\right)^{2} /\left(2 \ln \left(C V_{t}^{2}+1\right)\right)\right]$
$R$ variation: $\lambda_{R} \sum\left[\ln \left(R_{t} / \bar{R}\right)^{2}\right]$
$R$ sexratio: $\quad \lambda_{s}\left[\ln \left(\bar{R}_{M} / \bar{R}_{F}\right)^{2}\right]$
Trawl bycatch fishing mortalities : $\lambda_{t}\left[\ln \left(F_{t, t} / \bar{F}_{t}\right)^{2}\right]$
Pot female bycatch fishing mortalities: $\lambda_{p}\left[\ln \left(F_{t, f} / \bar{F}_{f}\right)^{2}\right]$
Trawl survey catchability: $(Q-\hat{Q})^{2} /\left(2 \sigma^{2}\right)$
where $R_{t}$ is the recruitment in year $t, \bar{R}$ the mean recruitment, $\bar{R}_{M}$ the mean male recruitment, $\bar{R}_{F}$ the mean female recruitment, $\bar{F}_{t}$ the mean trawl bycatch fishing mortality, $\bar{F}_{f}$ the mean pot female bycatch fishing mortality, $Q$ summer trawl survey catchability, and $\sigma$ the estimated standard deviation of $Q$ (all scenarios) or each of six growth increment parameters for scenario 2.
For BSFRF total survey biomass, $C V$ is the survey $C V$ plus $A V$, where $A V$ is additional $C V$ and estimated in the model.
Weights $\lambda_{j}$ are assumed to be 500 for retained catch biomass, and 100 for all bycatch biomasses, 2 for recruitment variation, 10 for recruitment sex ratio, 0.2 for pot female bycatch fishing mortality, and 0.1 for trawl bycatch fishing mortality. These $\lambda_{j}$ values correspond to CV values of $0.03,0.07$, $0.53,0.23,3.34$, and 12.14 , respectively, representing prior assumptions about the accuracy of the observed catch biomass data.

## d. Population State in Year 1.

The total abundance and proportions for the first year are estimated in the model.

## e. Parameter estimation framework:

i. Parameters estimated independently

Basic natural mortality, length-weight relationships, and mean growth increments per molt were estimated independently outside of the model. Mean length of recruits to the model depends on growth and was assumed to be 72.5 for both males and females. High grading parameters $h_{t}$ were estimated to be 0.2785 in 2005, 0.0440 in 2006, 0.0197 in 2007, 0.0198 in 2008, 0.0337 in 2009, 0.0153 in 2010, 0.0113 in 2011, 0.0240 in 2012, 0.0632 in 2013, 0.1605 in 2014, 0.07 in 2015, 0.0826 in 2016, and 0.0749 in 2017, based on the proportions of discarded legal males to total caught legal males. Handling mortality rates were set to 0.2 for the directed pot fishery, 0.25 for the Tanner crab fishery, 0.5 for the groundfish fixed gear fishery, and 0.8 for the groundfish trawl fishery.

## (1). Natural Mortality

Based on an assumed maximum age of 25 years and the $1 \%$ rule (Zheng 2005), basic $M$ was estimated to be 0.18 for both males and females. Natural mortality in a given year, $M_{t}$, equals to $M+M m_{t}$ (for males) or $M+M f_{t}$ (females). One value of $M m_{t}$ during 1980-1985 was estimated and two values of $M f_{t}$ during 1980-1984 and 1976-79, 1985-93 were estimated in the model for scenarios.

## (2). Length-weight Relationship

Length-weight relationships for males and females were as follows:
Immature Females: $\quad W=0.000408 L^{3.127956}$
Ovigerous Females: $W=0.003593 L^{2.666076}$
Males:

$$
\begin{equation*}
W=0.0004031 L^{3.141334} \tag{A19}
\end{equation*}
$$

where $W$ is weight in grams, and $L C L$ in mm .

## (3). Growth Increment per Molt

A variety of data are available to estimate male mean growth increment per molt for Bristol Bay RKC. Tagging studies were conducted during the 1950s, 1960s and 1990s, and mean growth increment per molt data from these tagging studies in the 1950s and 1960s were analyzed by Weber and Miyahara (1962) and Balsiger (1974). Modal analyses were conducted for the data during 1957-1961 and the 1990s (Weber 1967; Loher et al. 2001). Mean growth increment per molt may be a function of body size and shell condition and vary over time (Balsiger 1974; McCaughran and Powell 1977); however, for simplicity, mean growth increment per molt was assumed to be only a function of body size in the models. Tagging data were used to estimate mean growth increment per molt as a function of pre-molt length for males (Figure A2). The results from modal analyses of 1957-1961 and the 1990s were used to estimate mean growth increment per molt for immature females during 1975-1993 and 1994-2017, respectively, and the data presented in Gray (1963) were used to estimate those for mature females for scenarios 1, 1n and 2 (Figure A2). To make a smooth transition of growth increment per molt from immature to mature females, weighted growth increment averages of $70 \%$ and $30 \%$ at 92.5 mm CL pre-molt length and $90 \%$ and $10 \%$ at 97.5 mm CL were used, respectively, for mature and immature females during 1983-1993. These percentages are roughly close to the composition of maturity. During 1975-1982, females matured at a smaller size, so the growth increment per molt as a function of length was shifted to smaller increments. Likewise, during 1994-2017, females matured at a slightly higher size, so the growth increment per molt was shifted to high increments for immature crab (Figure A2). Once mature, the growth increment per molt for male crab decreases slightly and annual molting probability decreases, whereas the growth increment for female crab decreases dramatically but annual molting probability remains constant at 1.0 (Powell 1967).

## (4). Sizes at Maturity for Females

The NMFS collected female reproductive condition data during the summer trawl surveys. Mature females are separated from immature females by a presence of egg clutches or egg cases. Proportions of mature females at $5-\mathrm{mm}$ length intervals were summarized and a
logistic curve was fitted to the data each year to estimate sizes at $50 \%$ maturity. Sizes at $50 \%$ maturity are illustrated in Figure A3 with mean values for three different periods (1975-82, 1983-93, and 1994-2017).

## (5). Sizes at Maturity for Males

Although size at sexual maturity for Bristol Bay red king crab males has been estimated (Paul et al. 1991), there are no data for estimating size of functional maturity collected in the natural environment. Sizes at functional maturity for Bristol Bay male RKC have been assumed to be 120 mm CL (Schmidt and Pengilly 1990). This is based on mating pair data collected off Kodiak Island (Figure A4). Sizes at maturity for Bristol Bay female RKC are about 90 mm CL, about 15 mm CL less than Kodiak female RKC (Pengilly et al. 2002). The size ratio of mature males to females is 1.3333 at sizes at maturity for Bristol Bay RKC, and since mature males grow at much larger increments than mature females, the mean size ratio of mature males to females is most likely larger than this ratio. Size ratios of the large majority of Kodiak mating pairs were less than 1.3333, and in some bays, only a small proportion of mating pairs had size ratios above 1.3333 (Figure A4).

In the laboratory, male RKC as small as 80 mm CL from Kodiak and Southeast Alaska can successfully mate with females (Paul and Paul 1990). But few males less than 100 mm CL were observed to mate with females in the wild. Based on the size ratios of males to females in the Kodiak mating pair data, setting 120 mm CL as a minimum size of functional maturity for Bristol Bay male RKC is proper in terms of managing the fishery.

## (6). Potential Reasons for High Mortality during the Early 1980s

Bristol Bay red king crab abundance had declined sharply during the early 1980s. Many factors have been speculated for this decline: (i) completely wiped out by fishing: the directed pot fishery, the other directed pot fishery (Tanner crab fishery), and bottom trawling; and (ii) high fishing and natural mortality. With the survey abundance, harvest rates in 1980 and 1981 were among the highest, thus the directed fishing definitely had a big impact on the stock decline, especially legal and mature males. However, for the sharp decline during 1980-1984 for males, 3 out of 5 years had low mature harvest rates. During the 1981-1984 decline for females, 3 out of 4 years had low mature harvest rates. Also pot catchability for females and immature males are generally much lower than for legal males, so the directed pot fishing alone cannot explain the sharp decline for all segments of the stock during the early 1980s.

Red king crab bycatch in the eastern Bering Sea Tanner crab fishery is another potential factor (Griffin et al. 1983). The main overlap between Tanner crab and Bristol Bay red king crab is east of $163^{\circ} \mathrm{W}$. No absolute red king crab bycatch estimates are available until 1991. So there are insufficient data to fully evaluate the impact. Retained catch and potlifts from the eastern Bering Sea Tanner crab fishery are illustrated in Figure A5. The observed red king crab bycatch in the Tanner crab fishery during 1991-1993 and total potlifts east of $163^{\circ} \mathrm{W}$ during 1968 to 2005 were used to estimate the bycatch mortality in the current model. Because winter sea surface temperatures and air temperatures were warmer (which means a lower handling mortality rate) and there were fewer potlifts during the early 1980s than during the early 1990s, bycatch in the Tanner crab fishery is unlikely to have been a main factor for the sharp decline of Bristol Bay red king crab.

Several factors may have caused increases in natural mortality. Crab diseases in the early 1980s were documented by Sparks and Morado (1985), but inadequate data were collected to examine their effects on the stock. Stevens (1990) speculated that senescence may be a factor because many crab in the early 1980s were very old due to low temperatures in the 1960s and early 1970s. The biomass of the main crab predator, Pacific cod, increased about 10 times during the late 1970s and early 1980s. Yellowfin sole biomass also increased substantially during this period. Predation is primarily on juvenile and molting/softshell crab. But we lack stomach samples in shallow waters (juvenile habitat) and during the period when red king crab molt. Also cannibalism occurs during molting periods for red king crab. High crab abundance in the late 1970s and early 1980s may have increased the occurrence of cannibalism.

Overall, the likely causes for the sharp decline in the early 1980s are combinations of the above factors, such as pot fisheries on legal males, bycatch, and predation on females and juvenile and sublegal males, senescence for older crab, and disease for all crab. In our model, we estimated one mortality parameter for males and another for females during 1980-1984. We also estimated a mortality parameter for females during 1976-1979 and 1985-1993. These three mortality parameters are additional to the basic natural mortality of $0.18 \mathrm{yr}^{-1}$, all directed fishing mortality, and non-directed fishing mortality. These three mortality parameters could be attributed to natural mortality as well as undocumented nondirected fishing mortality. The model fit the data much better with these three parameters than without them.
ii. Parameters estimated conditionally

The following model parameters were estimated for male and female crab: total recruits for each year (year class strength $R_{t}$ for $t=1976$ to 2018), total abundance in the first year (1975), growth parameter $\beta$, and recruitment parameter $\beta_{r}$ for males and females separately. Molting probability parameters $\beta$ and $L_{50}$ were also estimated for male crab. Estimated parameters also include $\beta$ and $L_{50}$ for retained selectivity, $\beta$ and $L_{50}$ for potdiscarded female selectivity, $\beta$ and $L_{50}$ for pot-discarded male and female selectivities from the eastern Bering Sea Tanner crab fishery, $\beta$ and $L_{50}$ for groundfish trawl discarded selectivity, $\varphi, \kappa$ and $\gamma$ for pot-discarded male selectivity, and $\beta$ for trawl survey selectivity and $L_{50}$ for trawl survey male and females separately. The NMFS survey catchabilities $Q$ for some scenarios were also estimated. Three selectivity parameters were estimated for the survey data from the Bering Fisheries Research Foundation. Annual fishing mortalities were also estimated for the directed pot fishery for males (1975-2017), pot-discarded females from the directed fishery (1990-2017), pot-discarded males and females from the eastern Bering Sea Tanner crab fishery (1991-93, 2013-15), and groundfish trawl discarded males and females (1976-2017). Three additional mortality parameters for $M m_{t}$ and $M f_{t}$ were also estimated. Some estimated parameters were constrained in the model. For example, male and female recruitment estimates were forced to be close to each other for a given year.

## f. Definition of model outputs.

i. Biomass: two population biomass measurements are used in this report: total survey biomass (crab >64 mm CL) and mature male biomass (males >119 mm CL). Mating time is assumed to Feb. 15.
ii. Recruitment: new entry of number of males in the $1^{\text {st }}$ seven length classes ( $65-99 \mathrm{~mm} \mathrm{CL}$ ) and new entry of number of females in the $1^{\text {st }}$ five length classes ( $65-89 \mathrm{~mm} \mathrm{CL}$ ).
iii. Fishing mortality: full-selected instantaneous annual fishing mortality rate at the time of fishery.

Figure A1. Estimated capture probabilities for NMFS Bristol Bay red king crab trawl surveys by Weinberg et al. (2004) and the Bering Sea Fisheries Research Foundation surveys.

Figure A2. Mean growth increments per molt for Bristol Bay red king crab. Note: "tagging"--based on tagging data; "mode"---based on modal analysis. The female growth increments per molt are for scenarios $1,1 \mathrm{n}$ and 2 .

Figure A3. Estimated sizes at $50 \%$ maturity for Bristol Bay female red king crab from 1975 to 2008. Averages for three periods (1975-82, 1983-93, and 1994-08) are plotted with a line.

Figure A4. Histograms of carapace lengths (CL) and CL ratios of males to females for male shell ages $\leq 13$ months of red king crab males in grasping pairs; Powell's Kodiak data. Upper plot: all locations and years pooled; middle plot: location 11; lower plot: locations 4 and 13. Sizes at maturity for Kodiak red king crab are about 15 mm larger than those for Bristol Bay red king crab. (Doug Pengilly, ADF\&G, pers. comm.).

Figure A5. Retained catch and potlifts for total eastern Bering Sea Tanner crab fishery (upper plot) and the Tanner crab fishery east of $163^{\circ} \mathrm{W}$ (bottom).

Appendix B. Recruitment Breakpoint Analysis in May 2017

## Introduction

SSC asked authors to conduct a recruitment breakpoint analysis similar to that conducted for eastern Bering Sea Tanner crab in 2013 (Stockhausen 2013). We obtained the R codes from Dr. William (Buck) Stockhausen of NMFS and slightly modified them to conduct the analysis for Bristol Bay red king crab for better understanding the temporal change of stock productivity and the recruitment time series used for overfishing/overfished definitions. Results from assessment model scenario 2d are used for this analysis. We are very grateful for the help of Dr. Stockhausen for this analysis.

## Methods

The methods are the same as Punt et al. (2014) and Stockhausen (2013). Stock productivity is represented by $\ln (R / M M B)$, where $R$ is recruitment and $M M B$ is mature male biomass, with recruitment lagging to the brood year of mature biomass. Let $y_{t}=\ln (R / M M B)$ and $y_{t}$ can be estimated directly from the stock assessment model as observed values or from a stock-recruitment model as $\hat{y}_{t}$. For Ricker stock-recruitment models,
$\hat{y}_{t}=\alpha_{1}+\beta_{1} \cdot M M B \quad t<b$,
$\hat{y}_{t}=\alpha_{2}+\beta_{2} \cdot M M B \quad t \geq b$,
where $\alpha_{1}$ and $\beta_{1}$ are the Ricker stock-recruit function parameters for the early time period before the potential breakpoint in year $b$ and $\alpha_{2}$ and $\beta_{2}$ are the parameters for the time period after the breakpoint in year $b$. For Beverton-Holt stock-recruitment models,

$$
\begin{array}{ll}
\hat{y}_{t}=\alpha_{1}-\log \left(1+e^{\beta_{1}} \cdot M M B\right) & t<b, \\
\hat{y}_{t}=\alpha_{2}+\log \left(1+e^{\beta_{2}} \cdot M M B\right) & t \geq b, \tag{2}
\end{array}
$$

where $\alpha_{1}$ and $\beta_{1}$ are the Beverton-Holt stock-recruit function log-transformed parameters for the early time period before the potential breakpoint in year $b$ and $\alpha_{2}$ and $\beta_{2}$ are the log-transformed parameters for the time period after the breakpoint in year $b$.

A maximum likelihood approach is used to estimate stock-recruitment model and error parameters. Because $y_{t}$ is measured with error, the negative log-likelihood function is
$-\ln (L)=0.5 \cdot \ln (|\boldsymbol{\Omega}|)+0.5 \cdot \sum_{t} \sum_{j}\left(y_{t}-\hat{y}_{t}\right) \cdot\left[\boldsymbol{\Omega}^{-1}\right]_{, j} \cdot\left(y_{j}-\hat{y}_{j}\right)$,
where $\Omega$ contains observation and process error as

$$
\begin{equation*}
\boldsymbol{\Omega}=\mathbf{O}+\mathbf{P}, \tag{4}
\end{equation*}
$$

where $\mathbf{O}$ is the observation error covariance matrix estimated from the stock assessment model and $\mathbf{P}$ is the process error matrix and is assumed to reflect a first-order autoregressive process to have $\sigma^{2}$ on the diagonal and $\sigma^{2} \rho^{|t-j|}$ on the off-diagonal elements. $\sigma^{2}$ represents process error variance and $\rho$ represents the degree of autocorrelation.

For each candidate breakpoint year $b$, the negative $\log$ likelihood value of equation (3) is minimized with respect to the six model parameters: $\alpha_{1}, \beta_{1}, \alpha_{2}, \beta_{2}, \ln (\sigma)$ and $\tan (\rho)$. The minimum
time span considered as a potential regime is 5 years. Each brood year from 1980 to 2005 is evaluated as a potential breakpoint $b$ using time series of $\ln (\mathrm{R} / \mathrm{MMB})$ and MMB for brood years 1975-2010. A model with no breakpoint is also evaluated. Models with different breakpoints are then ranked using AICc (AIC corrected for small sample size; Burnham and Anderson 2004),

$$
\begin{equation*}
A I C_{c}=-2 \cdot \ln (L)+\frac{2 \cdot k \cdot(k+1)}{n-k-1} \tag{5}
\end{equation*}
$$

where $k$ is the number of parameters and $n$ is the number of observations. Using AICc, the model with the smallest AICc is regarded as the "best" model among the set of models evaluated. Different models can be compared in terms of $\theta_{m}$, the relative probability (odds) that the model with the minimum AICc score is a better model than model $m$, where

$$
\begin{equation*}
\theta_{m}=\exp \left(\left[\left(A I C c_{m}-A I C c_{\text {min }}\right) / 2\right] .\right. \tag{6}
\end{equation*}
$$

## Results

Results are summarized in Tables B1-B4 and Figures B1-B6. Discarding the implausible breakpoint year of 1980 for the Ricker model due to implausible stock-recruitment model parameters, both Ricker model and Beverton-Holt model result in the same breakpoint brood year of 1986, which corresponds to recruitment year of 1992. The model with no breakpoint (i.e., a single time period) is about 5 times less probable than the 1986 breakpoint model for BevertonHolt stock-recruitment models and about eight times less probable for Ricker stock-recruitment relationships, which may suggest a possible change in stock productivity from the early high period to the recent low period. Alternative breakpoint brood years of 1980-1985 for both Ricker and Beverton-Holt models are also reasonably reported. Both Ricker and Beverton-Holt stockrecruitment models fit the data poorly.

## Discussion

A recruitment breakpoint analysis was conducted on Bristol Bay red king crab by Punt et al. (2014) with data from 1968 to 2010 to estimate a breakpoint brood year of 1984, corresponding to recruitment year of 1990, which is two years earlier than our estimate, even though our results show that brood year of 1984 is also a likely breakpoint. The different time series of data may explain the different results. Our data start in 1975 and have only two brood-year data points before the regime shift of 1976/77 and thus we cannot detect any stock productivity changes due to the 1976/77 regime shift because of lack of data. Without the early data, the fits of stock-recruitment models to the data are also more poorly.

Time series of estimated recruitment during 1984-present have been used to compute Bmsy proxy. The mean recruitment with scenario 2 d during 1984-present is 17.77 million of crab, compared to the mean recruitment of 15.45 million of crab during 1992-present, about $13.0 \%$ reduction (Figure $12(2 d)$ ). If the estimated breakpoint year is used to set the new recruitment time series, estimated Bmsy proxy will be correspondingly lower than the current estimated value.

## Appendix C. Simple B0 Analysis

Ideally, a stock-recruitment relationship and impacts of environmental factors on recruitment are developed before doing B0 analysis. For Bristol Bay red king crab, there is hardly any relationship between estimated recruits and MMB (Figure 14a). The impacts of environmental factors on recruitment have not been quantified. We simply computed B0 values over time using the same recruitment time series estimated from the assessment model through setting all directed and bycatch fishing mortality to be zero. Figure C 1 shows the time series of estimated B0, MMB with fishing, and ratios of MMB to B0 for scenario 18.0. As expected, estimated B0 values change greatly over time.

Figure D1. Estimated B0, MMB with fishing, and ratios of MMB/B0 from 1975 to 2018 for scenario 18.0 for Bristol Bay red king crab.

# 2018 Stock Assessment and Fishery Evaluation Report for the Tanner Crab Fisheries of the Bering Sea and Aleutian Islands Regions 

\author{

#### Abstract

THIS INFORMATION IS DISTRIBUTED SOLELY FOR THE PURPOSE OF PREDISSEMINATION PEER REVIEW UNDER <br> APPLICABLE INFORMATION QUALITY GUIDELINES. IT HAS NOT BEEN FORMALLY DISSEMINATED BY NOAA FISHERIES/ALASKA FISHERIES SCIENCE CENTER AND SHOULD NOT BE CONSTRUED TO REPRESENT ANY AGENCY <br> DETERMINATION OR POLICY

}

## Executive Summary

## 1. Stock: species/area.

Southern Tanner crab (Chionoecetes bairdi) in the eastern Bering Sea (EBS).

## 2. Catches: trends and current levels.

Legal-sized male Tanner crab are caught and retained in the directed (male-only) Tanner crab fishery in the EBS. The NPFMC annually determines the overfishing limit (OFL) and acceptable biological catch (ABC) levels for Tanner crab in the EBS, while the Alaska Department of Fish and Game (ADFG) determines the total allowable catch (TAC) separately for areas east and west of $166^{\circ} \mathrm{W}$ longitude in the Eastern Subdistrict of the Bering Sea District Tanner crab Registration Area J. Following rationalization of the Bering Sea and Aleutian Islands (BSAI) crab fisheries in 2005/06, the directed fishery for Tanner crab was open through 2009/10, after which time it was determined that the stock was overfished in the EBS and directed fishing was closed. Prior to the closure, the retained catch averaged 770 t per year between 2005/06-2009/10. The directed fishery was re-opened in 2013/14 following determinations by NMFS in 2012 that the stock was rebuilt and no longer overfished and by ADFG that the stock met state harvest guidelines for opening the fishery. ADFG set the TAC at $1,645,000 \mathrm{lbs}(746 \mathrm{t})$ for the area west of $166^{\circ} \mathrm{W}$ and at $1,463,000 \mathrm{lbs}\left(664 \mathrm{t}\right.$ ) for the area east of $166^{\circ} \mathrm{W}$. On closing, $79.6 \%$ (594 t) of the TAC was taken in the western area while $98.6 \%$ ( 654 t ) was taken in the eastern area.

TACs were steadily increased for the next two years, with concomitant increasing harvests. In 2014/15, TAC was set at $6,625,000 \mathrm{lbs}(2,329 \mathrm{t})$ for the area west of $166^{\circ} \mathrm{W}$ and at $8,480,000 \mathrm{lbs}(3,829 \mathrm{t})$ for the area east of $166^{\circ} \mathrm{W}$. On closing, $77.5 \%(2,329 \mathrm{t})$ of the TAC was taken in the western area while $99.6 \%$ ( $3,829 \mathrm{t}$ ) were taken in the eastern area. In 2015/16, TAC was set at $11,272,000 \mathrm{lbs}(5,113 \mathrm{t})$ for the eastern area and $8,396,000 \mathrm{lbs}(3,808 \mathrm{t})$ for the western area. On closing, essentially $100 \%$ of the TAC was taken in both areas $(11,268,885 \mathrm{lbs}[5,111 \mathrm{t}]$ in the eastern area, $8,373,493 \mathrm{lbs}[3,798 \mathrm{t}]$ in the western area based on the 5/20/2016 in-season catch report).

Although the NPFMC determined an OFL of almost $60,000,000 \mathrm{lbs}(\sim 25,000 \mathrm{t})$ based on the 2016 assessment (Stockhausen, 2016), mature female Tanner crab biomass fell below the threshold set in the State of Alaska's harvest strategy for opening the fishery; consequently, the fishery was closed and the TAC was set to 0 . Thus, no directed harvest occurred in 2016/17. In 2017/18, ADFG determined that a directed fishery could occur in the area west of 1660 W longitude. The TAC was set at 2,500,200 lbs $(1,130 \mathrm{t})$, of which $100 \%$ was taken.

In addition to legal-sized males, females and sub-legal males are taken in the directed fishery as bycatch and must be discarded. Discarding of legal-sized males also occurs, primarily because the minimum size preferred by processors is larger than the minimum legal size but also because "old shell" crab are less desirable than "new shell" males. Tanner crab are also taken as bycatch in the snow crab and Bristol Bay
red king crab fisheries, in the groundfish fisheries and, to a very minor extent, in the scallop fishery. Over the last five years, the snow crab fishery has been the major source of Tanner crab bycatch among these fisheries, averaging $1,500 \mathrm{t}$ for the 5 -year period 2012/13-2016/17. Bycatch in the snow crab fishery in $2017 / 18$ was $1,120 \mathrm{t}$. The groundfish fisheries have been the next major source of Tanner crab bycatch over the same five year time period, averaging 360 t . Bycatch in the groundfish fisheries in 2017/18 was 143 t . Excluding the scallop fishery, the Bristol Bay red king crab fishery has typically been the smallest source of Tanner crab bycatch among these fisheries, averaging 85 t over the 5 -year time period. In 2017/18, this fishery accounted for 182 t of Tanner crab bycatch.

In order to account for mortality of discarded crab, handling mortality rates are assumed to be $32.1 \%$ for Tanner crab discarded in the crab fisheries, $50 \%$ for Tanner crab in the groundfish fisheries using fixed gear, and $80 \%$ for Tanner crab discarded in the groundfish fisheries using trawl gear to account for differences in gear and handling procedures used in the various fisheries.

## 3. Stock biomass: trends and current levels relative to virgin or historic levels

For EBS Tanner crab, spawning stock biomass is expressed as mature male biomass (MMB) at the time of mating (mid-February). From the author's preferred model (Model 18C2a), estimated MMB for 2017/18 was 47.0 thousand $t$ (Table 33; Appendix I7, Figure 3). This was smaller than those for the past three years (58.7, 61.0, and 57.7 thousand t , respectively), but it remains above the very low levels seen in the mid-1990s to early 2000s (1990 to 2005 average: 16.8 thousand t). However, it is considerably below model-estimated historic levels in the late 1970s (1975-1980 average: 72.2 thousand $t$ ) before it declined through 1985.

## 4. Recruitment: trends and current levels relative to virgin or historic levels.

From the author's preferred model (Model 18C2a), the estimated total recruitment for 2017/18 (the number of crab entering the population on July 1) is 662.47 million crab (Table 36; Appendix I7, Figure 1). Although this value is highly uncertain, it follows a similarly high estimate for 2016/17 (354.6 million crab). The average 5 -year recruitment prior to 2016/17 was only 68.3 million crab while the longterm (1982+) mean is 202.6 million crab.

## 5. Management performance

Historical status and catch specifications for eastern Bering Sea Tanner crab.

| Year | Tier $^{\mathbf{A}}$ | $\mathbf{B}_{\mathbf{M S Y}^{\mathbf{A}}}$ | Current <br> $\mathbf{M M B}^{\mathbf{A}}$ | $\mathbf{B}^{\mathbf{B} / \mathbf{B M S Y}^{\mathbf{A}}}$ | $\mathbf{F}_{\mathbf{F F L}^{\mathbf{A}}}{ }_{\left(\mathbf{y r}^{-1}\right)}$ | Years to <br> define <br> $\mathbf{B}_{\mathbf{M S Y}^{\mathbf{A}}}$ | Natural <br> Mortality $^{\mathbf{A}, \mathbf{B}}$ <br> $\left(\mathbf{y r}^{-1}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | 3 a | 65.74 | 140.66 | 2.14 | 0.61 | $1982-2014$ | 0.23 |
| $2015 / 16$ | 3 a | 59.06 | 118.38 | 2.00 | 0.58 | $1982-2015$ | 0.23 |
| $2016 / 17$ | 3 a | 56.54 | 99.95 | 1.77 | 0.79 | $1982-2016$ | 0.23 |
| $2017 / 18$ | 3 a | 64.30 | 103.70 | 1.49 | 0.75 | $1982-2017$ | 0.23 |
| $2018 / 19$ | 3 a | 48.21 | 51.87 | 1.08 | 0.93 | $1982-2018$ | 0.23 |

[^1]Current male spawning stock biomass (MMB), as projected for 2018/19, is estimated at 23.53 thousand t . $\mathrm{B}_{\text {MSY }}$ for this stock is calculated to be 21.87 thousand t , so MSST is 10.93 thousand t . Because current MMB > MSST, the stock is not overfished. Total catch mortality (retained + discard mortality in all fisheries, using a discard mortality rate of 0.321 for pot gear and 0.8 for trawl gear) in 2017/18 was 2.39 thousand t , which was less than the OFL for 2016/17 (25.42 thousand t ); consequently overfishing did not occur. The OFL for 2018/19 based on the author's preferred model (Model 18C2a) is 16.76 thousand t . The $\mathrm{ABC}_{\text {max }}$ for 2018/19, based on the $\mathrm{p}^{*} \mathrm{ABC}$, is 16.44 thousand t . In 2014, the SSC adopted a $20 \%$ buffer to calculate ABC for Tanner crab to incorporate concerns regarding model uncertainty for this stock. Based on this buffer, the ABC would be 13.41 thousand t .

## 7. Rebuilding analyses summary.

The EBS Tanner crab stock was found to be above MSST (and $\mathrm{B}_{\text {MSY }}$ ) in the 2012 assessment (Rugolo and Turnock, 2012b) and was subsequently declared rebuilt. The stock remains not overfished. Consequently no rebuilding analyses were conducted.

## A. Summary of Major Changes

1. Changes (if any) to the management of the fishery.

At the March, 2015 SOA Board of Fish (BOF) meeting, the Board adopted a revised harvest strategy for Tanner crab in the Bering Sea District ${ }^{1}$, wherein the TAC for the area east of $166^{\circ} \mathrm{W}$ longitude would be based on a minimum preferred harvest size of 127 mm CW ( 5.0 inches), including the lateral spines. Formerly, this calculation was based on a minimum preferred size of 140 mm CW ( 5.5 inches). The TAC in the area west of $166^{\circ} \mathrm{W}$ longitude continues to be based on a minimum preferred harvest size of 127 mm CW (including lateral spines).

The directed Tanner crab fishery east of $166^{\circ} \mathrm{W}$ longitude was closed in 2017/18, as in 2016/17, because mature female Tanner crab biomass failed to meet the criteria defined in the SOA's harvest strategy to open the fisheries. However, a directed fishery was conducted in the area west of $166^{\circ} \mathrm{W}$ longitude.

## 2. Changes to the input data

The following table summarizes data sources that have been updated for this assessment:

[^2]Updated data sources.

| Data source | Data types | Time frame | Notes | Agency |
| :---: | :---: | :---: | :---: | :---: |

## 3. Changes to the assessment methodology.

Following a considerable development effort and substantial review by the CPT at the January 2017 Modeling Workshop and the May 2017 CPT Meeting, with additional review by the SSC at its February and June 2017 meetings, a new modeling "framework", TCSAM02, was recommended by the CPT at its May 2017 meeting (and approved by the SSC at its June 2017 meeting) for use in the 2017/18 assessment. This framework was used again for this assessment. TCSAM02, while based on the previous assessment model (TCSAM2013), constitutes a completely rewritten code library for the Tanner crab assessment model. Results presented at the May 2017 CPT meeting demonstrated that TCSAM02 could be configured to exactly match results from the TCSAM2013 code, thus providing continuity with the old model code.

The 2017 assessment model (B2b in that assessment), built on the 2016 model by: 1) fitting EBS modelincrement data inside the model to inform growth parameters, b) estimating separate retention functions for three time periods (pre-1997/98, 2005/06-2009/10, and 2013/14-2015/16), and c) estimating the asymptotic value for the fraction of male crab retained in the directed fishery (in the same three time periods as (b)), rather than assuming it was 1 (i.e., $100 \%$ retention at large sizes).

The author-recommended model scenario proposed here, 18C2a, differs rather substantially from the 2017 assessment model by: 1) fixing NMFS EBS bottom trawl survey catchability and selectivity parameters in the $1982+$ time period to ones equivalent to those from Somerton and Otto (1999)'s socalled "underbag" experiment; 2) adding a likelihood component to fit annual male maturity ogives determined from chela height-to-carapace width ratios in the NMFS survey; and 3) eliminating fits to survey biomass and size composition data for male crab classified as mature/immature based on a maturity ogive determined outside the model and instead fitting to time series of aggregated male survey biomass and abundance, as well as to male size compositions classified by shell condition. In addition, revised time series data for retained and total catch abundance and biomass since 1990/91 were provided by ADFG for the directed Tanner crab, snow crab and Bristol Bay red king crab fisheries and incorporated into model parameter estimation.

## 4. Changes to the assessment results

Given the fairly substantial changes in model configuration and input data, the results from the author's preferred model this year (Model 18C2a) are surprisingly similar to those of the previous assessment (see Appendix J for a visual comparison of population trajectories from the two models). Average recruitment (1982-present) was estimated at 214 million in last year's model, whereas it is estimated at 199 million in the author's preferred model this year. $\mathrm{F}_{\text {MSY }}$ is larger this year ( $0.93 \mathrm{yr}^{-1}$ this year vs. $0.75 \mathrm{yr}^{-1}$ last year), while $\mathrm{B}_{\text {MSY }}$ was estimated somewhat smaller than last year ( 21.87 thousand t vs. 29.17 thousand t ).

## B. Responses to SSC and CPT Comments

1. Responses to the most recent two sets of SSC and CPT comments on assessments in general.

June 2018 SSC Meeting
No general comments.
May 2018 Crab Plan Team Meeting
No general comments.
October 2017 SSC Meeting
No general comments.
September 2017 Crab Plan Team Meeting
No general comments.
2. Responses to the most recent two sets of SSC and CPT comments specific to the assessment. [Note: for continuity with the previous assessment, the following includes comments prior to the most recent two sets of comments.]

June 2018 SSC Meeting
The SSC endorsed the CPT suggestions from its May meeting.
Response: none.
The SSC requested an evaluation of all parameters estimated to be at or very near bounds, or substantially limited by priors (unless those priors can be logically defended).
Response: See response above to general comments from the June 2017 SSC Meeting.

## May2018 Crab Plan Team Meeting

The CPT outlined a number of alternative models built on the 2017 assessment model (2017AM) as the base model to be evaluated.
Response: The CPT referred to these models as 2018B0, 2018B1, 2018B2, 2018B3, 2018B4 and 2018B5. These models were all run for this assessment, but renamed as 18A, 18B, 18C0, 18C1, 18D0, and 18D1, where " 18 " refers to the assessment year, $\mathrm{A} / \mathrm{B} / \mathrm{C} / \mathrm{D}$ refers to different datasets included in the likelihood, and $0 / 1$ refers to whether (1) or not (0) survey abundance time series were included in the fitting process in addition to survey biomass time series. 2017AM is subsequently referred to herein as 17AM. In addition to the alternative model scenarios requested by the CPT, several additional scenarios were also run: 17AMu, 18C0a, 18C1a, 18C2a, and 18C3a. Scenario 17AMu represents the 2017 assessment model re-run with revised (i.e., "u"pdated) data for the crab fisheries. The "a" in the remaining scenarios refers to ones in which the likelihood component for male maturity ogive data was down-weighted, whereas " 2 " and " 3 " refer to fixing the survey catchability and selectivity parameters to match ones from Somerton and Otto (1999)'s underbag experiment.

## October 2017 SSC Meeting

Comment: "The SSC endorses all of the CPT recommendations with respect to the poor fits to some of the retained catch time series, poor fits to the size composition data for retained catch and survey data, and issues with the total directed fishery selectivity curve for males (in particular the 1996 'outlier')." Response: With respect to the 1996 'outlier', this was a result of the combination of a very small sample size for the 1996 size compositions and the using the mean size-st-50\%-selected for 1991-1996 as the value for the size-at- $50 \%$-selected prior to 1991. Because the sample size for 1996 was small, the 1996 size-at- $50 \%$-selected essentially became a free parameter uninformed by the 1996 data but sensitive to changes in the overall likelihood through changes in the mean value. Regarding the other issues, see the responses to CPT comments below.

## September 2017 CPT Meeting

Comment: "The model fits total catch well, but does a poorer job in fitting retained catch, catch of females, and catch in the bycatch fisheries."
Response: Catch of females was improved by estimating a female-specific offset to fully-selected male capture rates in the fisheries. There appears to be a conflict in the model between fitting total (male) catch and retained catch in the directed fishery. In this assessment, I've explored the use of varying the estimated retention function annually and within time blocks, as well as the possibility that retention is not $100 \%$ for the largest male crab (i.e., the retention function asymptotes at less than 1). These options seem to reduce the conflict, but not eliminate it.

## C. Introduction

## 1. Scientific name.

Chionocoetes bairdi.Tanner crab is one of five species in the genus Chionoecetes (Rathbun, 1924). The common name "Tanner crab" for C. bairdi (Williams et al. 1989) was recently modified to "southern Tanner crab" (McLaughlin et al. 2005). Prior to this change, the term "Tanner crab" had also been used to refer to other members of the genus, or the genus as a whole. Hereafter, the common name "Tanner crab" will be used in reference to "southern Tanner crab".

## 2. Description of general distribution

Tanner crabs are found in continental shelf waters of the north Pacific. In the east, their range extends as far south as Oregon (Hosie and Gaumer 1974) and in the west as far south as Hokkaido, Japan (Kon 1996). The northern extent of their range is in the Bering Sea (Somerton 1981a), where they are found along the Kamchatka peninsula (Slizkin 1990) to the west and in Bristol Bay to the east.

In the eastern Bering Sea (EBS), the Tanner crab distribution may be limited by water temperature (Somerton 1981a). The unit stock is that defined across the geographic range of the EBS continental shelf, and managed as a single unit (Fig. 1). C. bairdi is common in the southern half of Bristol Bay, around the Pribilof Islands, and along the shelf break, although males less than the industry-preferred size ( $>125 \mathrm{~mm}$ CW ) and ovigerous and immature females of all sizes are distributed broadly from southern Bristol Bay northwest to St. Matthew Island (Rugolo and Turnock, 2011a). The southern range of the cold water congener the snow crab, C. opilio, in the EBS is near the Pribilof Islands (Turnock and Rugolo, 2011). The distributions of snow and Tanner crab overlap on the shelf from approximately $56^{\circ}$ to $60^{\circ} \mathrm{N}$, and in this area, the two species hybridize (Karinen and Hoopes 1971).

## 3. Evidence of stock structure

Tanner crabs in the EBS are considered to be a separate stock distinct from Tanner crabs in the eastern and western Aleutian Islands (NPFMC 1998). Somerton (1981b) suggests that clinal differences in some biological characteristics may exist across the range of the unit stock. These conclusions may be limited since terminal molt at maturity in this species was not recognized at the time of that analysis, nor was stock movement with ontogeny considered. Biological characteristics estimated based on comparisons of length frequency distributions across the range of the stock, or on modal length analysis over time may be confounded as a result.

Although the State of Alaska's (SOA) harvest strategy and management controls for this stock are different east and west of $166^{\circ} \mathrm{W}$, the unit stock of Tanner crab in the EBS appears to encompass both regions and comprises crab throughout the geographic range of the NMFS bottom trawl survey. Strong evidence is lacking that the EBS shelf is home to two distinct, non-intermixing, non-interbreeding stocks that should be assessed and managed separately.

## 4. Life history characteristics

## a. Molting and Shell Condition

Tanner crabs, like all crustaceans, normally exhibit a hard exoskeleton of chitin and calcium carbonate. This hard exoskeleton requires individuals to grow through a process referred to as molting, in which the individual sheds its current hard shell, revealing a new, larger exoskeleton that is initially soft but which rapidly hardens over several days. Newly-molted crab in this "soft shell" phase can be vulnerable to predators because they are generally torpid and have few defenses if discovered. Subsequent to hardening, an individual's shell provides a settlement substrate for a variety of epifaunal "fouling" organisms such as barnacles and bryozoans. The degree of hard-shell fouling was once thought to correspond closely to post-molt age and led to a classification of Tanner crab by shell condition (SC) in survey and fishery data similar to that described in the following table (NMFS/AFSC/RACE, unpublished):

| Shell Condition <br> Class | $\quad$ Description |
| :---: | :--- |
| 0 | pre-molt and molting crab |
| 1 | carapace soft and pliable |
| 2 | carapace firm to hard, clean |
| 3 | carapace hard; topside usually yellowish brown; thoracic sternum and underside of legs yellow <br> with numerous scratches; pterygostomial and bronchial spines worn and polished; dactyli on <br> meri and metabranchial region rounded; epifauna (barnacles and leech cases) usually present <br> but not always. |
| 5 | carapace hard, topside yellowish-brown to dark brown; thoracic sternum and undersides of legs <br> data yellow with many scratches and dark stains; pterygostomial and branchial spines rounded <br> with tips sometimes worn off; dactyli very worn, sometimes flattened on tips; spines on meri <br> and metabranchial region worn smooth, sometimes completely gone; epifauna most always <br> present (large barnacles and bryozoans). |
| 5 | conditions described in Shell Condition 4 above much advanced; large epifauna almost <br> completely covers crab; carapace is worn through in metabranchial regions, pterygostomial <br> branchial spines, or on meri; dactyli flattened, sometimes worn through, mouth parts and eyes <br> sometimes nearly immobilized by barnacles. |

Although these shell classifications continue to be applied to crab in the field, it has been shown that there is little real correspondence between post-molt age and shell classifications SC 3 through 5, other than that they indicate that the individual has probably not molted within the previous year (Nevisi et al, 1996). In this assessment, crab classified into SCs 3-5 have been aggregated as "old-shell" crab, indicating that these are crab likely to have not molted within the previous year. In a similar fashion, crab classified in SCs $0-2$ have been combined as "new shell" crab, indicating that these are crab have certainly (SCs 0 and 1 ), or are likely to have (SC 2), molted within the previous year.

## b. Growth

Work by Somerton (1981a) estimated growth for EBS Tanner crab based on modal size frequency analysis of Tanner crab in survey data assuming no terminal molt at maturity. Somerton's approach did not directly measure molt increments and his findings are constrained by not considering that the progression of modal lengths between years was biased because crab ceased growing after their terminal molt to maturity.

Growth in immature Tanner crab larger than approximately 25 mm CW proceeds by a series of annual molts, up to a final (terminal) molt to maturity (Tamone et al., 2007). Rugolo and Turnock (2012a) derived growth relationships for male and female Tanner crab used as priors for estimated growth parameters in this (and previous) assessments from data on observed growth in males to approximately 140 mm carapace width (CW) and in females to approximately 115 mm CW that were collected near Kodiak Island in the Gulf of Alaska (Munk, unpublished.; Donaldson et al. 1981). Rugolo and Turnock (2010) compared the resulting growth per molt (gpm) relationships with those of Stone et al. (2003) for Tanner crab in southeast Alaska in terms of the overall pattern of gpm over the size range of crab and found that the pattern of gpm for both males and females was characterized by a higher rate of growth to an intermediate size ( $90-100 \mathrm{~mm} \mathrm{CW}$ ) followed by a decrease in growth rate from that size thereafter. Similarly-shaped growth curves were found by Somerton (1981a) and Donaldson et al. (1981), as well.

Molt increment data was collected for Tanner crab in the EBS during 2015, 2016, and 2017 in cooperative research between NMFS and the Bering Sea Research Foundation (R. Foy, NMFS, pers. comm.). Previous analysis of the data suggests it is not substantially different from that obtained near Kodiak Island (Stockhausen, 2017). This data is incorporated in the assessment model to inform inferred growth trajectories in all of the alternative models evaluated in this assessment.

## c. Weight at Size

Weight-at-size relationships used in this assessment were revised in 2014 based on a comprehensive reevaluation of data from the NMFS EBS Bottom Trawl Survey (Daly et al., 2014). Weight-at-size is described by a power-law model of the form $w=a \cdot z^{b}$, where $w$ is weight in kg and $z$ is size in mm CW (Daly et al., 2016; table below). Parameter values are presented in the following table:

| sex | maturity | $a$ | $b$ |
| :---: | :---: | :---: | :---: |
| males |  | 0.000270 | 3.022134 |
| females | immature <br> (non-ovigerous) <br> mature <br> (ovigerous) | 0.000562 | 2.816928 |

## d. Maturity and Reproduction

It is now generally accepted that both Tanner crab males (Tamone et al. 2007) and females (Donaldson and Adams 1989) undergo a terminal molt to maturity, as in most majid crabs. Maturity in females can be determined visually rather unambiguously from the relative size of the abdomen. Females usually undergo their terminal molt from their last juvenile, or pubescent, instar while being grasped by a male (Donaldson and Adams 1989). Subsequent mating takes place annually in a hard shell state (Hilsinger 1976) and after extruding the female's clutch of eggs. While mating involving old-shell adult females has been documented (Donaldson and Hicks 1977), fertile egg clutches can be produced in the absence of males by using sperm stored in the spermathacae (Adams and Paul 1983, Paul and Paul 1992). Two or more consecutive egg fertilization events can follow a single copulation using stored sperm to selffertilize the new clutch (Paul 1982, Adams and Paul 1983), although egg viability decreases with time and age of the stored sperm (Paul 1984).

Maturity in males can be classified either physiologically or morphometrically, but is not as easily determined as with females. Physiological maturity refers to the presence or absence of spermataphores in the gonads whereas morphometric maturity refers to the presence or absence of a large claw (Brown and Powell 1972). During the molt to morphometric maturity, there is a disproportionate increase in the size of the chelae in relation to the carapace (Somerton 1981a). The ratio of chela height (CH) to carapace width (CW) has been used to classify male Tanner crab as to morphometric maturity. While many earlier studies on Tanner crabs assumed that morphometrically mature male crabs continued to molt and grow, there is now substantial evidence supporting a terminal molt for males (Otto 1998, Tamone et al. 2007). A consequence of the terminal molt in male Tanner crab is that a substantial portion of the population may never achieve legal size (NPFMC 2007). In this assessment, for the first time, several model scenarios are considered in which size-specific annual proportions of immature to mature male crab in the NMFS EBS bottom trawl survey, based on classification using CH:CW ratios, are fit to inform size-specific probabilities of terminal molt.

Although observations are lacking in the EBS, seasonal differences have been observed between mating periods for pubescent and multiparous females in the Gulf of Alaska and Prince William Sound. There, pubescent molting and mating takes place over a protracted period from winter through early summer, whereas multiparous mating occurs over a relatively short period during mid April to early June (Hilsinger 1976, Munk et al. 1996, and Stevens 2000). In the EBS, egg condition for multiparous Tanner crabs assessed between April and July 1976 also suggested that hatching and extrusion of new clutches for this maturity state began in April and ended sometime in mid-June (Somerton 1981a).

## e. Fecundity

A variety of factors affect female fecundity, including somatic size, maturity status (primiparous vs. multiparous), age post terminal molt, and egg loss (NMFS 2004). Of these factors, somatic size is the most important, with estimates of 89 to 424 thousand eggs for females 75 to 124 mm CW , respectively
(Haynes et al. 1976). Maturity status is another important factor affecting fecundity, with primiparous females being only $\sim 70 \%$ as fecund as equal size multiparous females (Somerton and Meyers 1983). The number of years post maturity molt, and whether or not, a female has had to use stored sperm from that first mating can also affect egg counts (Paul 1984, Paul and Paul 1992). Additionally, older senescent females often carry small clutches or no eggs (i.e., are barren) suggesting that female crab reproductive output is a concave function of age (NMFS 2004).

## f. Size at Maturity

Rugolo and Turnock (2012b) estimated size at $50 \%$ mature for females (all shell classes combined) from data collected in the NMFS bottom trawl survey at 68.8 mm CW , and 74.6 mm CW for new shell females. For males, Rugolo and Turnock (2012a) estimated classification lines using mixture-of-tworegressions analysis to define morphometric maturity for the unit Tanner crab stock, and for the sub-stock components east and west of $166^{\circ} \mathrm{W}$, based on chela height and carapace width data collected during the 2008 NMFS bottom trawl survey. These rules were then applied to historical survey data from 1990-2007 to apportion male crab as immature or mature based on size (Rugolo and Turnock, 2012b). Rugolo and Turnock (2012a) found no significant differences between the classification lines of the sub-stock components (i.e., east and west of $166^{\circ} \mathrm{W}$ ), or between the sub-stock components and that of the unit stock classification line. Size at $50 \%$ mature for males (all shell condition classes combined) was estimated at 91.9 mm CW, and at 104.4 mm CW for new shell males. By comparison, Zheng and Kruse (1999) used knife-edge maturity at $>79 \mathrm{~mm}$ CW for females and $>112 \mathrm{~mm}$ CW for males in development of the current SOA harvest strategy.

## g. Mortality

Due to the lack of age information for crab, Somerton (1981a) estimated mortality separately for individual EBS cohorts of immature and adult Tanner crab. Somerton postulated that age five crab (mean $\mathrm{CW}=95 \mathrm{~mm}$ ) were the first cohort to be fully recruited to the NMFS trawl survey sampling gear and estimated an instantaneous natural mortality rate of 0.35 for this size class using catch curve analysis. Using this analysis with two different data sets, Somerton estimated natural mortality rates of adult male crab from the fished stock to range from 0.20 to 0.28 . When using CPUE data from the Japanese fishery, estimates of M ranged from 0.13 to 0.18 . Somerton concluded that estimates of M from 0.22 to 0.28 obtained from models that used both the survey and fishery data were the most representative.

Rugolo and Turnock (2011a) examined empirical evidence for reliable estimates of oldest observed age for male Tanner crab. Unlike its congener the snow crab, information on longevity of the Tanner crab is lacking. They reasoned that longevity in a virgin population of Tanner crab would be analogous to that of the snow crab, where longevity would be at least 20 years, given the close analogues in population dynamic and life-history characteristics (Turnock and Rugolo 2011a). Employing 20 years as a proxy for longevity and assuming that this age represented the upper 98.5 th percentile of the distribution of ages in an unexploited population, M was estimated to be 0.23 based on Hoenig's (1983) method. If 20 years was assumed to represent the $95 \%$ percentile of the distribution of ages in the unexploited stock, the estimate for M was 0.15 . Rugolo and Turnock (2011a) adopted $\mathrm{M}=0.23$ for both male and female Tanner because the value corresponded with the range estimated by Somerton (1981a), as well as the value used in the analysis to estimate new overfishing definitions underlying Amendment 24 to the Crab Fishery Management Plan (NPFMC 2007).

## 5. Brief summary of management history.

A complete summary of the management history is provided in the ADFG Area Management Report appended to the annual SAFE. Fisheries have historically taken place for Tanner crab throughout their range in Alaska, but currently only the fishery in the EBS is managed under a federal Fishery Management Plan (FMP; NPFMC 2011). The plan defers certain management controls for Tanner crab to the State of Alaska, with federal oversight (Bowers et al. 2008). The State of Alaska manages Tanner crab
based on registration areas divided into districts. Under the FMP, the state can adjust districts as needed to avoid overharvest in a particular area, change size limits from other stocks in the registration area, change fishing seasons, or encourage exploration (NPFMC 2011).

The Bering Sea District of Tanner crab Registration Area J (Figure 1) includes all waters of the Bering Sea north of Cape Sarichef at $54^{\circ} 36^{\prime} \mathrm{N}$ and east of the U.S.-Russia Maritime Boundary Line of 1991. This district is divided into the Eastern and Western Subdistricts at $173^{\circ} \mathrm{W}$. The Eastern Subdistrict is further divided at the Norton Sound Section north of the latitude of Cape Romanzof and east of $168^{\circ} \mathrm{W}$ and the General Section to the south and west of the Norton Sound Section (Bowers et al. 2008). In this report, I use the terms "east region" and "west region" as shorthand to refer to the regions demarcated by $166^{\circ} \mathrm{W}$.

In March 2011, the Alaska Board of Fisheries (BOF) approved a new minimum size limit harvest strategy for Tanner crab effective for the $2011 / 12$ fishery. Prior to this change, the minimum legal size limit was $5.5 "(138 \mathrm{~mm}$ CW) throughout the Bering Sea District. The new regulations established different minimum size limits east and west of $166^{\circ} \mathrm{W}$. The minimum size limit for the fishery to the east of $166^{\circ} \mathrm{W}$ is now $4.8^{\prime \prime}(122 \mathrm{~mm} \mathrm{CW})$ and that to the west is $4.4^{\prime \prime}(112 \mathrm{~mm} \mathrm{CW})$, where the size measurement includes the lateral spines. For economic reasons, fishers may adopt larger minimum sizes for retention of crab in both areas, and the SOA's harvest strategy and total allowable catch (TAC) calculations are based on assumed minimum preferred sizes that are larger than the legal minimums. In 2011, these minimum preferred sizes were set at $5.5 "(140 \mathrm{~mm} \mathrm{CW})$ in the east and $5 "(127 \mathrm{~mm} \mathrm{CW})$ in the west, including the lateral spines. In 2015, following a petition by the crab industry, the BOF revised the minimum preferred size for TAC calculations in the area east of $166^{\circ} \mathrm{W}$ longitude to $5^{\prime \prime}(127 \mathrm{~mm} \mathrm{CW})$, the same as that in the western area. These new "preferred" sizes were used to set the TAC for the 2015/16 fishery season.

In assessments prior to 2016, the term "legal males" was used to refer to male crab $\geq 138 \mathrm{~mm} \mathrm{CW}$ (not including the lateral spines), although this was not strictly correct as it referred to the industry's "preferred" crab size in the east region, as well as to the minimum size in the east used in the SOA's harvest strategy for TAC setting. In this assessment, I use the term "legal males" to refer to crab 125 mm CW, the minimum "preferred" size used in both eastern and western areas the SOA's harvest strategy, and larger.

Landings of Tanner crab in the Japanese pot and tangle net fisheries were reported in the period 19651978, peaking at 19.95 thousand $t$ in 1969. The Russian tangle net fishery was prosecuted during 19651971 with peak landings in 1969 at 7.08 thousand t . Both the Japanese and Russian Tanner crab fisheries were displaced by the domestic fishery by the late-1970s (Table 1; Figure 3). Foreign fishing for Tanner crab ended in 1980.

The domestic Tanner crab pot fishery developed rapidly in the mid-1970s (Tables 1 and 2; Figure 3). Domestic US landings were first reported for Tanner crab in 1968 at 0.46 thousand $t$ taken incidentally to the EBS red king crab fishery. Tanner crab was targeted thereafter by the domestic fleet and landings rose sharply in the early 1970 s, reaching a high of 30.21 thousand $t$ in 1977/78. Landings fell sharply after the peak in 1977/78 through the early 1980s, and domestic fishing was closed in 1985/86 and 1986/87 due to depressed stock status. In 1987/88, the fishery reopened and landings rose again in the late-1980s to a second peak in 1990/91 at 18.19 thousand $t$, and then fell sharply through the mid-1990s. The domestic Tanner crab fishery was closed between 1996/97 and 2004/05 as a result of conservation concerns regarding depressed stock status. It re-opened in 2005/06 and averaged 0.77 thousand $t$ retained catch between 2005/06-2009/10 (Tables 1 and 2). For the 2010/11-2012/13 seasons, the State of Alaska closed directed commercial fishing for Tanner crab due to estimated female stock metrics being below thresholds adopted in the state harvest strategy. However, these thresholds were met in fall 2013 and the directed fishery was opened in $2013 / 14$. TAC was set at $1,645,000 \mathrm{lbs}(746 \mathrm{t})$ for the area west of $166^{\circ} \mathrm{W}$ and at
$1,463,000 \mathrm{lbs}(664 \mathrm{t})$ for the area east of $166^{\circ} \mathrm{W}$ in the State of Alaska's Eastern Subdistrict of Tanner crab Registration Area J. The fisheries opened on October 15 and closed on March 31. On closing, 79.6\% ( 594 t ) of the TAC had been taken in the western area while $98.6 \%$ ( 654 t ) had been taken in the eastern area. Prior to the closures, the retained catch averaged 770 t per year between 2005/06-2009/10. In 2014, TAC was set at $6,625,000 \mathrm{lbs}(3,005 \mathrm{t})$ for the area west of $166^{\circ} \mathrm{W}$ and at $8,480,000 \mathrm{lbs}(3,846 \mathrm{t})$ for the area east of $166^{\circ} \mathrm{W}$. On closing, $77.5 \%(2,329 \mathrm{t})$ of the TAC was taken in the western area while $99.6 \%$ $(3,829 \mathrm{t})$ were taken in the eastern area. In 2015 , TAC was set at $8,396,000 \mathrm{lbs}(3,808 \mathrm{t})$ in the western area and $11,272,000 \mathrm{lbs}(5,113 \mathrm{t})$ in the eastern area. On closing, essentially $100 \%$ of the TAC was taken in each area ( $3,798 \mathrm{t}$ in the west, $5,111 \mathrm{t}$ in the east). The total retained catch in 2015/16 (8,910 t) was the largest taken in the fishery since 1992/93 (Tables 1, 2; Figure 2). The directed fisheries in both areas were closed in 2016/17 because mature female biomass in the NMFS EBS Bottom Trawl Survey did not exceed the threshold set in the SOA's harvest strategy to allow them to open. Total retained catch was thus 0 in 2016/17. In 2017/18, the SOA allowed a limited directed fishery west of $166^{\circ} \mathrm{W}$ longitude but closed the fishery east of $166^{\circ} \mathrm{W}$. Essentially, the entire TAC $(1,130 \mathrm{t})$ was taken in 2017/18.

Bycatch and discard losses of Tanner crab originate from the directed pot fishery, non-directed snow crab and Bristol Bay red king crab pot fisheries, and the groundfish fisheries (Table 3; Figure 3). Within the assessment model, bycatch estimates are converted to discard mortality using assumed handling mortality rates of $32.1 \%$ for bycatch in the crab fisheries and $80 \%$ for bycatch in the groundfish fisheries. Bycatch was persistently high during the early-1970s; a subsequent peak mode of discard losses occurred in the early-1990s. In the early-1970s, the groundfish fisheries contributed significantly to total bycatch losses (although bycatch in the crab fisheries was undocumented at the time). From 1992/93 (when reliable crab fishery bycatch estimates are first available) to 2004/05, the groundfish fisheries accounted for the largest proportion of discard mortality. Since 2005/06, however, the crab fisheries have accounted for the largest proportion.

## D. Data

## 1. Summary of new information

ADFG provided revised values for retained catch abundance and biomass by shell condition from fish ticket data for 2005/06-2016/17, with new values for 2017/18 (Appendix A). This included a breakout of incidental retained Tanner crab catch in the snow crab and BBRKC fisheries; previously, only total retained catch (assumed taken in the directed fishery) had been provided. In general, incidental retained catch of Tanner crab in the snow crab and BBRKC fisheries has been very small compared with that from the directed fishery. Retained catch size composition data from "dockside" observer sampling in the directed fishery were updated by ADFG for 2013/14-2015/16 and new data for 2017/18 were provided (Appendix A).

Revised estimates of total catch (retained + discards) abundance and biomass in all three crab fisheries, based on "at-sea" crab observer sampling, were provided by sex and shell condition by ADFG for 1990/91-2016/17, with new estimates provided for 2017/18 (Appendix B). ADFG also provided size composition data from "at-sea" crab observer sampling by sex and shell condition for 1990/91-2017/18 (Appendix B). Revised estimates of total effort (potlifts) in the three crab fisheries were also provided for 1990/91-2016/17, with new estimates for 2017/18 (Appendix C).

Tanner crab bycatch data in the groundfish fisheries (abundance, biomass, size compositions) were extracted for 1991/92-2017/18 from the groundfish observer and AKRO databases on AKFIN (Appendix D). Results for 1991/92-2016/17 were slightly different than last year, reflecting small changes in the algorithms used to expand observed bycatch to total bycatch, as well as data editing. Although the bycatch data in the groundfish fisheries available by gear type, all model scenarios examined here fit the data aggregated over gear types (see below).

Swept-area abundance, biomass and size composition data from the 2018 NMFS EBS Bottom Trawl Survey were added to the assessment. Survey results for the assessment were calculated directly from the survey "crab haul" data files and station strata file to incorporate assessment criteria (e.g., excluding crab $<25 \mathrm{~mm} \mathrm{CW}$, aggregating crab > 185 mm CW into the upper-most size bin in size compositions) and facilitate comparisons across multiple areas and population categories. More details are provided in Appendices E and F.

Molt increment data from growth studies conducted in the EBS as cooperative research by NMFS and BSFRF are fit in the model scenarios included in this assessment. These data are described in more detail in Appendix G.

Finally, annual maturity ogives based on classification of male crab in the NMFS EBS bottom trawl survey using $\mathrm{CH}: \mathrm{CW}$ ratios are fit for the first time in a number of the model scenarios considered in this assessment. These data are described in more detail in Appendix H.

The following table summarizes data sources that have been updated for this assessment:

| Data source | Data types | Time frame | Notes | Agency |
| :---: | :---: | :---: | :---: | :---: |
| NMFS EBS Bottom Trawl Survey | area-swept abundance, biomass size compositions molt-increment data | $\begin{gathered} 1975-2018 \\ 1975-2018 \\ 1990+ \\ \hline \end{gathered}$ | recalculated, new recalculated, new new | NMFS |
| NMFS/BSFRF | molt-increment data | 2014-16 | same as 2017 | NMFS, BSFRF |
| Directed fishery | retained catch (numbers, biomass) | 2005/06-2017/18 | updated, new | ADFG |
|  | retained catch size compositions | 2013/14-2017/18 | updated | ADFG |
|  | effort | 2015/16, 2016/17 | updated, new | ADFG |
|  | total catch (abundance, biomass) | 1991/92-2017/18 | updated, new | ADFG |
|  | total catch size compositions | 1991/92-2017/18 | updated, new | ADFG |
| Snow Crab Fishery | effort | 1990/91-2017/18 | revised, new | ADFG |
|  | total bycatch (abundance, biomass) | 1990/91-2017/18 | revised, new | ADFG |
|  | total bycatch size compositions | 1990/91-2017/18 | revised, new | ADFG |
| Bristol Bay | effort | 1990/91-2017/18 | revised, new | ADFG |
| Red King Crab Fishery | total bycatch (abundance, biomass) | 1990/91-2017/18 | revised, new | ADFG |
|  | total bycatch size compositions | 1990/91-2017/18 | revised, new | ADFG |
| Groundfish Fisheries (all gear types) | total bycatch (abundance, biomass) total bycatch size compositions | $\begin{aligned} & 1991 / 92-2017 / 18 \\ & 1991 / 92-2017 / 18 \end{aligned}$ | revised, new updated, new | NMFS/AKFIN |

The following table summarizes the data coverage in the assessment model (color shading highlights different model time periods and data components):

## 2. Data presented as time series

For the data presented in this document, the convention is that 'year' refers to the year in which the NMFS bottom trawl survey was conducted (nominally July 1, yyyy), and fishery data are those subsequent to the survey (July 1, yyyy to June 30, yyyy+1)--e.g., 2015/16 indicates the 2015 bottom trawl survey and the winter 2015/16 fishery.

## a. Retained catch

Information on retained catch is also discussed in Appendix A. Retained catch in the directed fisheries for Tanner crab conducted by the foreign fisheries (Japan and Russia) and the domestic fleet, starting in 1965/66, is presented in Table 1 and Figure 2 by fishery year. More detailed information on retained catch in the directed domestic pot fishery is provided in Table 2, which lists total annual catches in numbers of crab and biomass (in lbs), as well as the SOA's Guideline Harvest Level (GHL) or Total Allowable Catch (TAC), number of vessels participating in the directed fishery, and the fishery season. Information from the Community Development Quota (CDQ) is included in the totals starting in 2005/06.

Directed fisheries for Tanner crab in the EBS began in 1965. Retained catch has followed a "boom-andbust" cycle over the years, with the fishery experiencing periods of rapidly increasing catches followed by rapidly declining ones, after which it is closed for a time during which the stock partially recovers. Retained catch increased rapidly from 1965 to 1975 , reaching $\sim 25,000 \mathrm{t}$ in 1970 . It declined to $\sim 13,000 \mathrm{t}$ in 1973/74 coinciding with the termination of Russian fishing and the beginning of the domestic pot fishery. It increased again, this time to its highest level, in 1977/78 ( $\sim 35,000 \mathrm{t})$ as the domestic fishery developed rapidly, but it subsequently declined again and the fishery was closed in 1985/86 and 1986/87. In the late 1980s and early 1990s, the fishery experienced another, somewhat smaller, "boom" followed by a "bust" and closure of the fishery from 1997/98 to 2004/05. From 2005/06 to 2009/10, the fishery experienced its smallest boom-and-bust cycle, peaking at only $\sim 1,000$ t retained catch, and was closed again from 2010/11 to 2012/13. The fishery was re-opened in 2013/14, and retained catch increased each subsequent year until 2016/17 as TACs increased (Figures 2 and 6). The retained catch for 2015/16 (8,910 t) was the largest since 1992/1993 (15,920 t; Table 1). However, ADFG closed the directed fishery in both areas for the 2016/17 fishing season because mature female biomass in the 2016 NMFS EBS bottom trawl survey did not meet the SOA's criteria for opening the fisheries. In 2017/18, ADFG allowed the fishery to commence in the western area (TAC was set at $1,130 \mathrm{t}$ ) but was closed in the eastern area. The directed fishery essentially caught the entire TAC.

## b. Information on bycatch and discards

Total catch estimates for Tanner crab in the directed Tanner crab, the snow crab, and the BBRKC fisheries are provided in Table 3 and Figure 3 based on ADFG "at-sea" crab observer sampling starting in $1992 / 93$. Annual bycatch in the groundfish fisheries, based on NMFS groundfish observer programs, is also available starting in 1973/74, but sex is undifferentiated. A value of 0.321 is used in the assessment model for "handling mortality" in the crab fisheries to convert observed bycatch to (unobserved) mortality (Stockhausen, 2014). For the groundfish fisheries, a value of 0.8 is used for handling mortality aggregated across gear types to reflect differences in groundfish gear effects and on-deck operations compared with the crab fleets. In previous assessments, estimates of "discards" were provided rather than estimates for "total catch", which allowed mortality associated with the handling process to be estimated outside the assessment model. While this generally remains true for bycatch in the groundfish and non-directed crab fisheries (most or all Tanner crab bycatch is discarded), "discard mortality" cannot be estimated outside the assessment model for males in the directed fishery.

Estimated bycatch mortality in the groundfish fisheries (without distinguishing gear type) was highest ( $\sim 15,000 \mathrm{t}$ ) in the early 1970s, but was substantially reduced by1977 to $\sim 2,000 \mathrm{t}$ with the curtailment of foreign fishing fleets (Stockhausen, 2017). It declined further in the 1980s (to ~500 t) but increased somewhat in the late 1980s to a peak of $\sim 2,000 \mathrm{t}$ in the early 1990 s before undergoing a slow but rather
steady decline to the present ( 255 t in 2016/17). Since reliable at-sea ADFG crab observer data has been available (1992), the snow crab fishery has consistently accounted for the highest fraction of bycatch mortality among the crab fisheries, followed by the directed fishery and the BBRKC fishery. Estimated bycatch mortality was highest for all crab fisheries in the early 1990s ( $\sim 12,000 \mathrm{t}$ total) but subsequently declined as (presumably) the stock declined and the directed fishery was curtailed. Since the directed fishery re-opened in 2013/14, bycatch mortality has averaged 325 t in the directed fishery, 554 t in the snow crab fishery, 32 t in the BBRKC fishery, and 309 t in the groundfish fisheries (Stockhausen, 2017).

In the crab fisheries, the largest component of bycatch occurs on males (Stockhausen, 1991). In the early 1990s, female bycatch ranged between 6 and $40 \%$ of the bycatch in the directed and snow crab fisheries. Since the directed fishery re-opened in 2013/14, the fraction of bycatch that is female has ranged between $2 \%$ and $6 \%$ in the directed fishery, between 0.3 and $3 \%$ in the BBRKC fishery, and has been below $1 \%$ in the snow crab fishery. Estimates of total groundfish bycatch are not currently available by sex.

## c. Catch-at-size for fisheries, bycatch, and discards

Retained (male) catch-at-size in the directed Tanner crab fishery from ADFG crab observer sampling is presented in Appendix A, Figures 7-8, by fishery region (and total) since the fishery re-opened in $2013 / 14$. These appear to indicate a shift to retaining somewhat smaller minimum sizes since 2013/14, compared with 2005/06-2009/10 (Stockhausen, 2017). In fact, the BOF in 2014/15, in response to a petition by industry, changed its harvest strategy for calculating TACs to reflect a smaller minimum industry-preferred size of 125 mm CW east of $166^{\circ} \mathrm{W}$ longitude.

Size compositions expanded to total catch (retained + discards) from at-sea crab fishery observer sampling in the directed fishery are presented by shell condition and fishery region in Appendix B, Figures 3-4 and 13-14, by sex. The male size compositions suggest that about half the males caught in the directed fishery in 2015/16 were less than the minimum preferred size of 125 mm CW . If old shell males really are males at least one year past their terminal molt (as assumed in the assessment model), the size compositions for these crab suggest that $30-50 \%$ of these crab (which will not grow) are less than the preferred size.

Size compositions expanded to total bycatch of Tanner crab in the snow crab fishery, based on at-sea crab fishery observer sampling, are presented by sex and shell condition in Appendix B, Figures 5-8 and 1518. Because this fishery is prosecuted further north and west, on average, than the directed fishery, its bycatch composition consists of somewhat smaller males than in the directed fishery. Conversely, the expanded bycatch size compositions for the BBRKC fishery tend to be shifted toward somewhat larger males than the directed fisheries because the BBRKC fishery is prosecuted further to the south and east on average than the directed fishery (Appendix B, Figures 9-12 and 19-22). Size compositions expanded to total bycatch based on observer sampling in the groundfish fisheries for 1991/92 to the present are shown in Appendix D, Figures 15-18. Size compositions prior to 1991/92 have not been expanded to total bycatch; thus, the scales are incompatible with those after 1990/91. Male bycatch size compositions in the snow crab fishery clearly reflect some sort of "dome-shaped" selectivity pattern (as assumed in the assessment model), with selectivity small for small and large males and highest for intermediate-sized males. In contrast, the BBRKC fishery appears to catch mostly larger Tanner crab males (consistent with asymptotic selection), while the groundfish fisheries take a wide range of sizes as bycatch.

Raw and input sample sizes (number of individuals measured) for the various fisheries are presented in Tables 4-8.

## d. Survey biomass estimates

Time series trends from the NMFS EBS bottom trawl survey suggest the Tanner crab stock in the EBS has undergone decadal-scale fluctuations (Tables 9-10, Appendix E Figures 1-14). Estimated biomass of mature crab in the survey time series started at its maximum ( $277,000 \mathrm{t}$ ) in 1975 , decreased rapidly to a
low ( $17,000 \mathrm{t}$ ) in 1986, and rebounded quickly to a smaller peak ( $157,000 \mathrm{t}$ ) in 1991 (Appendix E, Figure 5). After 1991, mature survey biomass decreased again, reaching a minimum of $13,100 \mathrm{t}$ in 1998. Recovery following this decline was slow and mature survey biomass did not peak again until 2008 ( $82,900 \mathrm{t}$ ), after which it has fluctuated more rapidly-decreasing within two years by almost $50 \%$ and reaching a minimum in $2010(44,600 \mathrm{t})$, followed by an increase of almost $50 \%$ to reach a peak in 2014 ( $97,300 \mathrm{t}$ ). The most recent trend in mature biomass (2014-2018) has been a declining one (Appendix E, Figure 6). Trends in the male and female components of mature survey biomass and abundance have primarily been in synchrony with one another, as have changes in the eastern and western fishery regions (east and west of $166^{\circ} \mathrm{W}$ longitude), although the magnitudes differ (Appendix E, Figures 5-8). Preferredsize male survey biomass and abundance has been declining east of $166^{\circ} \mathrm{W}$ (and in the EBS as a whole) since 2014, but was increasing up to 2016 in the west. In the west, it declined in 2017 and remains essentially unchanged in 2018 (Appendix E, Figures 9-12).

## e. Survey catch-at-length

Plots of survey size compositions for Tanner crab by sex and fishery region, expanded to total abundance by shell condition for males and maturity state for females, in Appendix E, Figures 13-15. The absence of small (new shell) male crab in the eastern region since 2009 is notable, as is the progression of a possible cohort through both regions starting in 2009. Similar to males, a cohort progression of immature females starting in 2009 is evident in both regions, although it is much clearer in the western region. It can also be tracked into the mature female size comps starting in 2013. A potential new cohort is also evident in the size comps for both sexes in the western region, but not the eastern region, in 2017 and 2018.

Observed sample sizes for the size compositions, aggregated to the EBS regional level used in the assessment, are presented in Table 11. Given the large number of individuals sampled, a sample size of 200 is used to fit survey size compositions in the assessment model to prevent convergence issues associated with using the actual sample sizes.

## f. Other time series data.

Spatial patterns of abundance in the 2012-2018 NMFS bottom trawl surveys are mapped in Appendix F for immature males, mature males, immature females, mature females and legal males. There has been some suggestion that an extensive cold pool in the middle region of the EBS shelf may act to diminish relative crab densities in this region, particularly for mature males. The cold pool on the EBS shelf was extensive during the 2017 survey but absent during the 2018 survey, but the distribution of mature males did not change remarkably (Appendix F, Figures 7-8).

Annual effort in the snow crab and BBRKC fisheries is used in the model to "project" bycatch fishing mortality rates backward in time from the period when data on bycatch in these fisheries exists (1992present). A table of annual effort (number of potlifts) is provided for the snow crab and BBRKC fisheries (Table 12; see Appendix C, as well).

Maturity ogives for male crab, using chela height to carapace width ratios to classify male crab on which chela height measurements have been taken during the NMFS EBS bottom trawl survey, are available for a number of years since 1990 (Appendix G). These data are used in a number of the model scenarios considered for this assessment to inform the size-specific probability of terminal molt by immature male crab.

## 3. Data which may be aggregated over time:

a. Growth-per-molt

Molt increment data collected for Tanner crab in 2015 and 2016 in the EBS is now fit in the model (see Appendix H), but it is assumed to reflect growth rates over the entire model period.

## b. Weight-at size

Weight-at-size relationships used in the assessment model for males, immature females, and mature females is depicted in Figure 4.
c. Size distribution at recruitment

The assumed size distribution for recruits to the population in the assessment model is presented in Figure 5.
4. Information on any data sources that were available, but were excluded from the assessment. The 1974 NMFS trawl survey was dropped entirely from the standardized survey dataset in 2015 due to inconsistencies in spatial coverage with the standardized dataset. Data collected on Tanner crab abundance and size compositions collected in BSFRF surveys are not yet incorporated in the assessment.

## E. Analytic Approach

## 1. History of modeling approaches for this stock

Prior to the 2012 stock assessment, Tanner crab was managed as a Tier-4 stock using a survey-based assessment approach (Rugolo and Turnock 2011b). The Tier 3 Tanner Crab Stock Assessment Model (TCSAM) was developed by Rugolo and Turnock and presented for review in February 2011 to the Crab Modeling Workshop (Martel and Stram 2011), to the SSC in March 2011, to the CPT in May 2011, and to the CPT and SSC in September 2011. The model was revised after May 2011 and the report to the CPT in September 2011 (Rugolo and Turnock 2011a) described the developments in the model per recommendations of the CPT, SSC and Crab Modeling Workshop through September 2011. In January 2012, the TCSAM was reviewed at a second Crab Modeling Workshop. Model revisions were made during the Workshop based on consensus recommendations. The model resulting from the Workshop was presented to the SSC in January 2012. Recommendations from the January 2012 Workshop and the SSC, as well as the authors' research plans, guided changes to the model. A model incorporating all revisions recommended by the CPT, the SSC and both Crab Modeling Workshops was presented to the SSC in March 2012.

In May 2012 and June 2012, respectively, the TCSAM was presented to the CPT and SSC to determine its suitability for stock assessment and the rebuilding analysis (Rugolo and Turnock 2012b). The CPT agreed that the model could be accepted for management of the stock in the 2011/12 cycle, and that the stock should be promoted to Tier-3 status. The CPT also agreed that the TCSAM could be used as the basis for rebuilding analyses to underlie a rebuilding plan developed in 2012. In June 2012, the SSC reviewed the model and accepted the recommendations of the CPT. The Council subsequently approved the SSC recommendations in June 2012. For 2011/12, the Tanner crab was assessed as a Tier-3 stock and the model was used for the first time to estimate status determination criteria and overfishing levels.

Modifications have been made to the TCSAM computer code to improve code readability, computational speed, model output, and user friendliness without altering its underlying dynamics and overall framework. A detailed description of the 2013 model (TCSAM2013) is presented in Appendix 3 of the 2014 SAFE chapter (Stockhausen, 2014). Following the 2014 assessment, the model code was put under version control using "git" software and is publicly available for download from the GitHub website ${ }^{2}$.

A new model "framework", TCSAM02, was reviewed by the CPT and SSC in May/June 2017 and adopted for use in subsequent assessments as a transition to Gmacs. The new framework is a completelyrewritten basis for the Tanner crab model: substantially different model scenarios can be created and run by editing model configuration files rather than modifying the underlying code itself. Most importantly, no time blocks are "hard-wired" into the code-any time blocks are defined in the configuration files. In

[^3]addition, the new frame work incorporates new data types (e.g., molt increment data, male maturity ogives), new survey data (e.g., the BSFRF surveys), and new fishery data (e.g., bycatch in the groundfish fisheries by gear type). The new model framework also incorporates status determination and OFL calculation directly within a model run, so a follow-on, stand-alone projection model does not need to be run, as with TCSAM2013. This approach has the added benefit of allowing a more complete characterization of model uncertainty in the OFL calculation, because the OFL calculations are now included in Markov Chain Monte Carlo (MCMC) evaluation of a model's posterior probability distribution. The code for the TCSAM02 model framework is publicly available on GitHub ${ }^{3}$.

## 2. Model Description

## a. Overall modeling approach

TCSAM02 is a stage/size-based population dynamics model that incorporates sex (male, female), shell condition (new shell, old shell), and maturity (immature, mature) as different categories into which the overall stock is divided on a size-specific basis. For details of the model, the reader is referred to Appendix K.

In brief, crab enter the modeled population as recruits following the size distribution in Figure 22. An equal (50:50) sex ratio is assumed at recruitment, and all recruits begin as immature, new shell crab. Within a model year, new shell, immature recruits are added to the population numbers-at-sex/shell condition/maturity state/size remaining on July 1 from the previous year. These are then projected forward to Feb. $15(\delta t=0.625 \mathrm{yr})$ and reduced for the interim effects of natural mortality. Subsequently, the various fisheries that either target Tanner crab or catch them as bycatch are prosecuted as pulse fisheries (i.e., instantaneously). Catch by sex/shell condition/maturity state/size in the directed Tanner crab, snow crab, BBRKC, and groundfish fisheries is calculated based on fishery-specific stage/sizebased selectivity curves and fully-selected fishing mortalities and removed from the population. The numbers of surviving immature, new shell crab that will molt to maturity are then calculated based on sex/size-specific probabilities of maturing, and growth (via molt) is calculated for all surviving new shell crab. Crab that were new shell, mature crab become old shell, mature crab (i.e., they don't molt) and old shell crab remain old shell. Population numbers are then adjusted for the effects of maturation, growth, and change in shell condition. Finally, population numbers are reduced for the effects of natural mortality operating from Feb. 15 to July $1(\delta t=0.375$ yr) to calculate the population numbers (prior to recruitment) on July 1.

Model parameters are estimated using a maximum likelihood approach, with Bayesian-like priors on some parameters and penalties for smoothness and regularity on others. Data components in the base model entering the likelihood include fits to mature survey biomass, survey size compositions, retained catch, retained catch size compositions, bycatch mortality in the bycatch fisheries, and bycatch size compositions in the bycatch fisheries.

## b. Changes since the previous assessment.

Since the 2017 assessment, two principal changes have been implemented in the TCSAM02 framework. The first is a change in the way so-called "devs" vectors are handled in the code. The second is the introduction of fits to annual maturity ogive data in the model likelihood and parameter optimization.
"Devs" vectors are vectors of model parameters that have the property that the elements of each vector sums to zero (hence "deviations"). Previously, this constraint was met by allowing n-1 elements of an nelement devs vector to be estimated, while the final element was fixed at the negative sum of the preceding elements. However, this presented difficulties when bounds were placed on the values the elements could take on. The new approach is to allow all elements of a devs vector to be freely-estimable,

[^4]but with a component in the likelihood that penalizes non-zero sums across the vector elements. This approach is similar in nature to that taken in ADMB to achieve similar behavior.

Fits to annual male maturity ogives can now be included in the model likelihood (modeled as a sizespecific binomial) in order to better estimate size-specific probabilities for immature crab to undergo terminal molt. This obviates, in particular, the need to impose an immature/mature classification on male crab in the NMFS survey whose chela heights have not been measured, as was done previously (e.g., Stockhausen, 2017).

## i. Methods used to validate the code used to implement the model

The TCSAM02 model framework was demonstrated to produce results that were exactly equivalent to those from the 2016 assessment model incorporating the changes listed in the previous table. TCSAM02 also underwent a review in July 2017 conducted by the Center for Independent Experts and has been further reviewed by the CPT in May 2017 and September 2017.

## 3. Model Selection and Evaluation

## a. Description of alternative model configurations

The model selected for the 2017 assessment (Model B2b from Stockhausen, 2017) provides the baseline model configuration for subsequent alternative model scenarios evaluated in this assessment. Here, the 2017 assessment model is designated "17AM". The following tables provide a summary of the baseline model configuration, 17AM, for this assessment.

Model 17AM: Description of model population processes and survey characteristics.

| process | time blocks | description |
| :---: | :---: | :---: |
| Population rates and quantities |  |  |
| Population built from annual recruitment |  |  |
| Recruitment | $\begin{aligned} & 1949-1974 \\ & 1975-2017 \end{aligned}$ | In-scale mean + annual devs constrained as AR1 process In-scale mean + annual devs |
| Growth | 1949-2016 | sex-specific <br> mean post-molt size: power function of pre-molt size <br> post-molt size: gamma distribution conditioned on pre-molt size |
| Maturity | 1949-2016 | sex-specific <br> size-specific probability of terminal molt <br> logit-scale parameterization |
| Natural mortalty | $\begin{aligned} & 1949-1979 \\ & 1985-2016 \\ & 1980-1984 \end{aligned}$ | estimated sex/maturity state-specific multipliers on base rate priors on multipliers based on uncertainty in max age estimated "enhanced mortality" period multipliers |
| Surveys |  |  |
| NMFS EBS trawl survey |  |  |
| male survey q | 1975-1981 | In-scale |
|  | 1982+ | In-scale w/ prior based on Somerton's underbag experiment |
| female survey q | 1975-1981 | In-scale |
|  | 1982+ | In-scale w/ prior based on Somerton's underbag experiment |
| male selectivity | 1975-1981 | ascending logistic |
|  | 1982+ | ascending logistic |
| female selectivity | 1975-1981 | ascending logistic |
|  | 1982+ | ascending logistic |

Model 17AM: Description of model fishery characteristics.

Model 17AM: Description of model likelihood components.

| Component | Type | Distribution | Likelihood |
| :---: | :---: | :---: | :---: |
| TCF: retained catch | abundance | -- | -- |
|  | biomass | norm2 | males only |
|  | size comp.s | multinomial | males only |
| TCF: total catch | abundance | -- | -- |
|  | biomass | norm2 | by sex |
|  | size comp.s | multinomial | by sex |
| SCF: total catch | abundance | -- | -- |
|  | biomass | norm2 | by sex |
|  | size comp.s | multinomial | by sex |
| RKF: total catch | abundance | -- | -- |
|  | biomass | norm2 | by sex |
|  | size comp.s | multinomial | by sex |
| GTF: total catch | abundance | -- | -- |
|  | biomass | norm2 | by sex |
|  | size comp.s | multinomial | by sex |
| NMFS survey | abundance | -- | -- |
|  | biomass | lognormal | by sex, for mature crab only |
|  | size comp.s | multinomial | by sex/maturity |
|  | chela height data | -- | -- |
| growth data | EBS only | gamma | by sex |

The following alternative model scenarios were evaluated as part of this assessment (previous names applied to these scenarios in the 2017 assessment and May 2018 CPT report are given in parentheses):

| model <br> scenario | number of <br> parameters | objective <br> function value | max gradient | description |
| :---: | :---: | :---: | :---: | :--- |
| 17AM (B2b) | 344 | $2,905.84$ | 0.0001 | 2017 assessment model |
| 17AMu | 344 | $3,014.71$ | 0.0007 | 17AM with updated crab fishery data |
| 18A (B0) | 357 | $3,139.58$ | 0.0010 | 17AMu with 2017/18 fishery data and 2018 NMFS survey data |

Scenarios 18A, 18B, 18C0, 18C1, 18D0 and 18D1 correspond to the scenarios B0, B1, B2, B3, B4 and B5 the CPT requested (at the May 2018 CPT meeting) be evaluated for this assessment. Several other scenarios (18C0a, 18C1a) were also run which considered changes to the weighting placed on fitting the male maturity ogive data in the likelihood, as well as scenarios (18C2a, 18C3a) which used fixed values to describe catchability and selectivity for the NMFS survey data after 1981 based on the Somerton and Otto underbag experiment (Somerton and Otto, 1999). These two latter scenarios were included because estimated values for survey catchability in the other scenarios were unrealistically small and led to what appear to be unrealistically high estimates of recruitment, population biomass and MMB, and population productivity for the Tanner crab stock. Using results from the underbag experiment at least provides an empirical basis for fixing the catchability and selectivity values in scenarios C2a and C3a.

The number of estimated parameters, the final value of the objective function for each converged scenario (each based on at least 1,200 jitter runs), and the maximum gradient of the objective function at the converged solution are also listed in the table above (18D1 did not converge). The total objective function values, however, cannot be directly compared between scenarios because each scenario fits different datasets.18C2a is the author's preferred model, as explained below.

The alternative scenarios listed above primarily incorporate the same model structure but differ in the datasets used to perform the parameter optimization. As noted above, however, scenarios 18C2a and 18C3a differ from the remaining scenarios in fixing, rather than estimating, values for NMFS survey catchabilities and selectivities in the 1982-2018 time frame based on Somerton and Otto (1999)'s underbag experiment.

Scenario 17AMu fits the revised crab fishery data provided by ADFG and groundfish fishery data provided by AKFIN through 2016/17 (see Appendices A, B, C) using the same model configuration as 17 AM , thus providing a means of evaluating the effects of the changes to the input data on model results. As discussed below, the effects are rather dramatic. 18A builds on 17AMu by including the new data for 2017/18. Additionally, as recommended by the CPT in May 2018, the probability of terminal molt for male crab was fixed at 0 for crab less than 60 mm CW and at 1 for crab > 150 in order to be more biologically realistic. Similarly, the probability of terminal molt for female crab less than 40 mm CW was fixed at 0.18 B builds on 18A and provides a bridging scenario by including fits to the male maturity ogive data from the NMFS EBS bottom trawl survey in the parameter optimization (even though Rugolo and Turnock's empirical maturity ogive is used to classify male abundance as immature/mature prior to input to the model).

Scenario 18C0 represents a distinct break with the previous scenarios because it removes the empirical maturity classification from the male survey data and fits total survey biomass by sex and size compositions by shell condition for males and maturity state and shell condition for females rather than fitting mature biomass by sex and size compositions by sex and maturity state. Scenario 18C0a reduces the weight placed on fits to the male maturity ogives in the model likelihood in 18C0 by a factor of 100 . Scenario 18C1 includes fits to male survey abundance by shell condition and female survey abundance by maturity state and shell condition, in addition to similar components of survey biomass. Scenario 18C1a reduces the weight placed on fits to the male maturity ogives in the model likelihood in 18 C 1 by a factor of 100 . Scenario 18C2a differs from 18C1a by fixing the survey catchability parameter values (Q's) and selectivities in the 1982-2018 time block to those estimated by Somerton in the "underbag" experiment for "males + immature females" and mature females, rather than estimating them as in prior scenarios. Scenario 18C3a is similar to 18C2a, but fixes the survey catchabilities in 1982-2018 for all crab to that estimated for "males + immature females" in the underbag experiment. Scenario 18D0 is similar to 18C0, except that the survey biomass and size composition components are aggregated over shell condition before being included in the model likelihood. Scenario 18D1 is similar that of 18D0, except that fits to survey abundance (aggregated across shell condition) are included by sex.

## b. Progression of results from the previous assessment to the preferred base model

The following table summarizes basic model results from the 2017 assessment model (17AM) and the 11 scenarios considered here:

| Model <br> Scenario | average recruitment millions | Final MMB 1000's t | $\begin{gathered} \text { BO } \\ \text { 1000's t } \end{gathered}$ | $\begin{aligned} & \text { Bmsy } \\ & \text { 1000's t } \end{aligned}$ | Fmsy | $\begin{gathered} \text { MSY } \\ \text { 1000's t } \end{gathered}$ | Fofl | OFL <br> 1000's t | $\begin{gathered} \text { projected } \\ \text { MMB } \\ 1000 \text { 's t } \end{gathered}$ | projected MMB <br> / Bmsy |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 17AM (B2b) | 213.96 | 80.58 | 83.34 | 29.17 | 0.75 | 12.26 | 0.75 | 25.42 | 43.32 | 1.49 |
| 17AMu | 371.11 | 136.48 | 111.38 | 38.98 | 1.25 | 18.03 | 1.25 | 50.85 | 63.55 | 1.63 |
| 18A | 391.22 | 114.10 | 120.00 | 42.00 | 1.22 | 19.24 | 1.22 | 42.01 | 53.87 | 1.28 |
| 18B | 464.60 | 124.18 | 130.45 | 45.66 | 2.61 | 22.35 | 2.61 | 55.40 | 48.01 | 1.05 |
| 18C0 | 536.07 | 122.84 | 124.39 | 43.54 | 3.06 | 24.32 | 3.04 | 56.15 | 43.25 | 0.99 |
| 18COa | 366.37 | 99.63 | 100.92 | 35.32 | 1.07 | 18.13 | 1.07 | 35.44 | 46.25 | 1.31 |
| 18C1 | 540.64 | 128.64 | 129.28 | 45.25 | 2.79 | 25.90 | 2.78 | 58.26 | 45.12 | 1.00 |
| 18C1a | 404.67 | 110.14 | 109.74 | 38.41 | 1.14 | 20.41 | 1.14 | 39.87 | 49.67 | 1.29 |
| 18C2a | 199.49 | 50.12 | 63.01 | 22.05 | 0.91 | 11.54 | 0.91 | 16.76 | 24.06 | 1.09 |
| 18C3a | 188.34 | 49.93 | 63.61 | 22.26 | 0.79 | 10.84 | 0.79 | 15.93 | 25.44 | 1.14 |
| 18D0 | 503.62 | 145.40 | 149.02 | 52.16 | 2.64 | 24.09 | 2.64 | 65.30 | 57.35 | 1.10 |

Scenario 18D1 is not included in the above table because, as mentioned above, the model failed to converge for this scenario. The author's preferred model, 18C2a, is highlighted for reference. All new model scenarios were evaluated using at least 1,200 runs with jittered initial parameter values to select the run with the smallest objective function value and smallest maximum gradient. The large number of runs
for each scenario were required because randomly-selected growth parameters were frequently inconsistent with positive growth. For each converged scenario, the selected run was re-run to invert the hessian and obtain standard deviations for parameter estimates. All models except 18D1 resulted in hessians that were invertible and provided uncertainty estimates associated with the parameter estimates.

As noted previously, the substantial differences in results between scenarios 17AM and 17AMu in the above table illustrate the rather dramatic impact the revised crab fishery data provided by ADFG has on this assessment. Both scenarios fit the (same) survey biomass data equally well (Figure 6), and both scenarios fit the different input fishery data equally well (Figures 7 and 8, illustrating fits to retained catch biomass and total catch biomass for males in the directed and snow crab fisheries). The changes are substantially driven by large changes ( $\sim x 0.5$ ) in estimated survey catchability from 17AM to 17 AMu (Figure 9) such that recruitment (Figure 10), mature biomass (Figure 11), and MSY-related quantities are higher using the revised data. Adding the 2017/18 data (scenario 18A) does not affect the previous fits to survey biomass (Figure 12), retained catch and total catch biomass for males in the directed and snow crab fisheries (Figures 13 and 14) or the BBRKC and groundfish fisheries (not shown). Estimated survey catchabilities in the 1982+ time frame are slightly smaller for 18A than 17AMu (Figure 15), but this has little to no effect on estimated trends in recruitment (Figure 16) and mature biomass (Figure 17). The small differences between the two scenarios in MSY-related quantities in the above table are primarily due to a slightly higher estimate of average recruitment from 18A driven by a very large estimate of recruitment ( $\sim 1$ billion crab) in 2018.

## c. Evidence of search for balance between realistic (but possibly over-parameterized) and simpler (but not realistic) models.

It was noted at the May 2018 CPT meeting that it was not biologically realistic that male Tanner crab less than 60 mm CW had undergone their terminal molt, although this was suggested by non-zero ratios of the abundance of mature, new shell male crab to all new shell males at sizes less than 60 mm CW based on chela height data collected in the NMFS EBS bottom trawl survey. It was similarly recognized that it was probably biologically unrealistic for female crab less than 40 mm CW to have undergone terminal molt. This actually resulted in simpler, but more realistic models, in scenarios where these constraints were implemented (scenarios 18B and subsequent).

## d. Convergence status and convergence criteria

Convergence in all models was assessed by running each model at least 1,200 times with randomlyselected ("jittered") initial parameter values for each run. For each model, a number of these jitter runs failed, primarily because the initial values for the growth parameters resulted in the mean post-molt size being smaller than the pre-molt size. Of those that converged, the run with the smallest objective function value and smallest maximum gradient was selected as the "converged" model, if it was also possible to invert the associated hessian and obtain standard deviation estimates for parameter values. Theoretically, all gradients at a minimum of the objective function would be zero. However, because numerical methods have finite precision, the numerical search for the minimum is terminated after achieving a minimum threshold for the max gradient or exceeding the maximum number of iterations. Typically, 5-10 jittered runs converged to the same minimum value, but sets of runs also converged to larger valuesemphasizing the need to jitter to evaluate convergence to the minimum objective function value in the first place.

## e. Sample sizes assumed for the compositional data

Input sample sizes used for compositional data are listed in Tables 4-8 for fishery-related size compositions. Input sample sizes for all survey size compositions were set to 200 , which was also the maximum allowed for the fishery-related sample sizes. Otherwise, input sample sizes were scaled as described in Stockhausen (2014, Appendix 5):

$$
S S_{y}^{i n p}=\min \left(200, \frac{S S_{y}}{(\overline{S S} / 200)}\right)
$$

where $\overline{S S}$ was the mean sample size for all males from dockside sampling in the directed fishery.

## f. Parameter sensibility

Limits were placed on all estimated parameters in all model scenarios primarily to provide ranges for jittering initial parameter values. Although these limits, for the most part, did not constrain parameter estimates in the converged models, some parameters were found to be at, or very close, to one of the bounds placed on them. These parameters are listed for the alternative scenarios in Tables 13 and 14 (values for all parameters other than annually-varying $\ln$-scale fishery capture rate deviations are listed in Tables 15-23). The CPT and SSC have both expressed concerns regarding parameters estimated at their bounds, as such results frequently violate assumptions regarding model convergence, parameter uncertainty estimates, and suggest that model suitability may be improved by widening the bounds or reparameterizing the model. The logit-scale parameter describing the retention of male crab at large (asymptotic) sizes prior to 1997 was estimated at its upper bound (15) in all model scenarios. Because retention can only go as high as 1 on the arithmetic scale, and a logit-scale value of 15 corresponds to an arithmetic scale value of 0.9999997 , this parameter can be fixed in future models. Many of the scenarios estimated survey catchability parameters at the lower bounds placed on them (Table 13; pQ[1], pQ[3], and $\mathrm{pQ}[4]$ ) and width of the selectivity function ( $\mathrm{pS} 2[2]$ and $\mathrm{pS4}[4]$ in Table 14), indicating that the data provides little information on absolute population size. These results provided the rationale for fixing the survey parameters to those from the Somerton and Otto (1999) underbag experiment.

A number of parameters related to fishery bycatch selectivity in the snow crab and BBRKC fisheries typically hit one of their bounds consistently across scenarios, as well (parameters for the size at $95 \%$ selected in the BBRKC fishery in different time blocks and parameters describing the slope of the descending limb of selectivity in the snow crab fishery). A number of other selectivity-related parameters, while not at one of their bounds, have large uncertainties associated with the estimates (e.g., the $95 \%$ selected size for female bycatch in the BBRKC fishery, Table 22). These may reflect indeterminancy between the estimated capture rate for fully-selected crab and these parameters in determining the effective capture rates on large crab.

Finally, it may be worthwhile noting that the beta parameter (pGrBeta[1]) determining the spread of potential molt increments for a given pre-molt size was estimated at its lower bound in all of the scenarios that did not fit survey abundance (17AMu, 18A, 18B, 18C0, 18C0a and 18D0), but in none which did (18C1, 18C2a, 18C3a).

Estimates of parameter uncertainty, approximations calculated by inverting the model hessian and using the "delta" method, were obtained from each converged model's ADMB "std" file (Tables 15-23). Extremely large uncertainties were obtained for parameters related to the NMFS trawl survey selectivity for females after 1981 for all scenarios that estimated these parameters, unless the estimates hit one of the bounds (Table19). Selectivity parameters for female bycatch in the BBRKC fishery in 1997-2004 also exhibited high uncertainty when the estimates were not hitting a bound.

## g. Criteria used to evaluate the model or to choose among alternative models

None of the model scenarios evaluated in this assessment were directly comparable using likelihood criteria because different datasets were fit, or different likelihood weights were used, in all scenarios. Consequently, the criteria used to evaluate the alternative models were based primarily on: 1) goodness of fit (assessed using RMSE for different datasets even when the datasets were not included in the likelihood), 2) parameter sensibility, and 3) biological realism.

The author's preferred model, 18C2a, fits all of the datasets reasonably well, incorporates empirical parameters for survey catchability and selectivity to determine absolute scale, and appear to yield more biologically-reasonable estimates of population size and stock productivity than other scenarios.

## h. Residual analysis

Residuals for the author's preferred model, Model 18C2a, are discussed below under the Results section.
i. Evaluation of the model(s)

Results from the "18" scenarios (i.e., scenarios 18A, 18B, 18C0, 18C0a, 18C1, 18C1a, 18C2a, 18C3a, and 18D0) are compared amongst each other in Appendix I, which is broken into 9 sections (I1-I9) which organize different categories of results in the following manner:

| Appendix | Description |
| :--- | :--- |
| I1 | fits to survey and fishery biomass and abundance |
| I2 | mean fits to survey size compositions; effective sample sizes |
| I3 | mean fits to fishery size compositions; effective sample sizes |
| I4 | fits to size compositions by year |
| I5 | fits to growth and male maturity ogive data |
| I6 | population processes (natural mortality rates, etc.) |
| I7 | population quantities (recruitment, population abundance and biomass) |
| I8 | survey characteristics (catchabilities, selectivities) |
| I9 | fishery characteristics (capture rates, selectivities) |

The models in all " 18 " scenarios matched the fishery retained catch and total catch biomass and abundance data time series nearly equally well (Figures I1.19-25; i.e., Appendix I1, Figures 19-25). Differences among the scenarios were more apparent in comparisons with survey abundance and biomass trends (Figures I1.1-18). The scenarios generally fit the data equally well after the early 1990's, with the largest differences occurring prior to that time. Scenarios 18C2a and 18C3a stood out from the others by following the large increase/decrease in abundance/biomass seen from 1987-1993.

All scenarios fit mean female survey size compositions reasonably well and in similar fashion (Appendix I2), but some differences existed for mean male survey size compositions, in particular for immature males (Figure I2.1) and for old shell males (Figure I2.5). 18A, which included fits to immature and mature male size compositions without fits to the male maturity ogives, had the best fit to the immature male size compositions whereas 18 C 2 a and 18 C 3 a tended to underpredict the proportion of immature males around 100 mm CW while the other scenarios overpredicted these proportions. All scenarios predicted mean proportions of new shell crab equally well, but 18C2a and 18C3a appeared to predict those mean proportions for old shell males somewhat more closely than the other scenarios (Figure I2.5). All scenarios predicted mean fishery size compositions equally well (Append I3). Comparison among the scenarios with annual size compositions (Appendix I4) generally reflects the observations regarding the fits to mean size compositions-and the scenarios generally either all do well, or all do poorly, at fitting a given annual size composition. That said, there are some "interesting"-ly poor fits to male survey size compositions by shell type at the start of the time series (late 1970s, early 1980s; see Figures I4.21 and I4.26) which may have to do with inconsistent classification of shell condition in the early years of the survey.

Scenario 18C3a exhibited the highest slope of mean post-molt size regarded as function of pre-molt size among all scenarios for both males and females, while the other scenarios were almost indistinguishable from one another (Figure I5.1). Scenarios 18C2a and 18C3a consistently estimated smaller probabilities of terminal molt for a given post-molt size than the other scenarios (Figures 15.4-8), indicating that male
crab that survived were more likely to grow to larger sizes before undergoing terminal molt in scenarios 18 C 2 a and 18 C 3 a than in the others.

Estimated natural mortality rates are shown in Figure I6.1. Mortality rates are assumed equal by sex for immature crab but are allowed to differ by sex for mature crab. Mortality rates for mature crab were estimated by sex across two time periods: 1949-1979/80+1985/86-2016/17 and 1980/81-1984/85. The latter period has been identified as a period of high natural mortality in the BBRKC stock (Zheng et al., 2012) and was identified as a separate period for Tanner crab in the 2012 assessment. Natural mortality rates for immature crab were similar across all scenarios, while they differed somewhat (more so in the "high" period) from one another for mature crab. 18C3a exhibited the highest rates for mature females across both time blocks while 18C2a estimated the highest rate on mature crab during the "high mortality" period.

The scenarios all exhibited similar temporal trends in recruitment but differed as to level (Figure I7.1). 18D0 consistently exhibited the largest recruitments, while 18C2a and 18C3a exhibited the smallest. Population abundance and biomass trends among the scenarios were similar to those for recruitment (Figures I7.2-3).

Fully-selected catchability in the NMFS EBS bottom trawl survey is estimated on a sex-specific basis in two time periods: 1975-81 and 1982+. All scenarios that estimated survey catchability in the 1975-81 time period yielded identical results for males, ending at the lower bound of 0.5 , as did most of the scenarios for female catchability in this time period (all except 18C2a and 18C3a; Figure I8.1). In the post-1981 time period, estimated survey catchability was lower than that in the earlier time period across all scenarios that estimated catchability (scenarios 18C2a and 18C3a fixed catchabilities in this time period). Male selectivities were similar across all scenarios in the post-1981 time period (and consequently estimated selectivities were similar to those from the underbag experiment), while female selectivity functions differed substantially at smaller sizes (Figure I8.2). When catchabilities and selectivity functions were combined as "capture probabilities" (Figure I8.3), the main factor for the differences between scenarios 18C2a and 18C3a and the other scenarios in characterizing the Tanner crab stock (i.e., recruitment and biomass trends) were apparent: the capture probabilities in the other scenarios were much smaller over all sizes, and with varied with size, than did those from 18C2a and 18C3a.

Given the previous results, it is unsurprising that, while temporal trends in fishery catchability were similar across all scenarios, scenarios 18C2a and 18C3a consistently exhibited the highest values across years for each fishery (Figures 19.1-4). Estimated selectivity functions estimated for the directed and bycatch fisheries were generally similar across scenarios (Figures I9.5-30), except for those for male bycatch in the snow crab fishery prior to 1997. Although these selectivity functions were all domeshaped, the level at which the plateau occurred was substantially lower than 1 for 18C3a.

The model scenarios examined here are all in good agreement on the relative scale of fluctuations in Tanner crab stock abundance and biomass, but they are not in good agreement on the overall absolute scale. The combination of estimated (fully-selected) survey catchability and survey selectivity (i.e., survey capture probabilities), would appear to be the driver behind the absolute scale for the model's predictions of Tanner crab stock biomass under any of these scenarios. However, the estimates of this scale are highly uncertain given that the relevant parameters are frequently estimated either at one of the bounds placed on the parameter or are highly uncertain. Although the situation is not new to this assessment, what little information was formerly available in the data regarding absolute scale seems to have diminished with the revised fishery data from ADFG. Time constraints on the assessment have not allowed anywhere near a full exploration of this issue, but given the past apparent sensitivity of this stock to fishing pressure (given several cycles of a closure following a period of high catches), the rather high exploitation rates ( $\mathrm{F}_{\mathrm{MSY}}$ ) and sustainable stock sizes ( $\mathrm{F}_{\text {OFL }}$ ) which many of the scenarios suggest for the

Tanner crab stock suggest it is necessary to impose tighter restrictions on survey capture probabilities. Scenarios 18C2a and 18C3a embody a simple, empirically-based approach to do so until further information (e.g., the BSFRF surveys) can be incorporated into the assessment that better defines absolute scale. Scenario 18C2a appears to fit the survey data somewhat better than 18C3a, and thus is the author's preferred model going forward.

## 4. Results (best model(s))

Model 18C2a was selected as the author's preferred model for the 2018 assessment.
a. List of effective sample sizes, the weighting factors applied when fitting the indices, and the weighting factors applied to any penalties.
Input and effective sample sizes for size composition data fit in the model are listed in Tables 26-31 from the 2017 assessment model and scenario 18C2a. A weighting factor of 20 (corresponding to a standard deviation of 0.158 ) was applied to all fishery catch biomass likelihood components to achieve close fits to catch biomass time series.

## b. Tables of estimates:

## i. All parameters

Parameter estimates and associated standard errors, based on inversion of the converged model's Hessian, are listed in Tables 15-23.
ii. Abundance and biomass time series, including spawning biomass and MMB.

Estimates for mature survey biomass, by sex, are listed in Table 32 and for mature biomass at mating, by sex, in Table 33 for the 2017 assessment model and the author's preferred model, 18C2a. Due to the size of the tables, the numbers at size for females and males by year in 5 mm CW size bins for scenario 18C2a are available online as zipped csv files (see Tables 34 and Table 35, respectively).
iii. Recruitment time series

The estimated recruitment time series from the 2017 assessment and Model 18C2a are listed in Table 36. The time series are compared graphically in Figure J1.
iv. Time series of catch divided by biomass.

A comparison of catch divided by biomass (i.e., exploitation rate) from the 2017 assessment and 18C2a is listed in Table 37.
c. Graphs of estimates

Graphs of estimates from the preferred scenario, 18C2a, are given in Appendix I. Most have been discussed above in the "Model Selection" section.
i. Fishery and survey selectivities, molting probabilities, and other schedules depending on parameter estimates.
Estimated natural mortality rates are shown in Figure I6-1. Mortality rates are assumed equal by sex for immature crab but are allowed to differ by sex for mature crab. Mortality rates for mature crab were estimated by sex across two time periods: 1949-1979/80+1985/86-2016/17 and 1980/81-1984/85. The latter period has been identified as a period of high natural mortality in the BBRKC stock (Zheng et al., 2012) and was identified as a separate period for Tanner crab in the 2012 assessment. Natural mortality rates for immature crab were estimated at $0.21 \mathrm{yr}^{-1}$ and, excluding the high mortality period, at $0.35 \mathrm{yr}^{-1}$ for mature crab. Estimated sex- and size-specific probabilities of the terminal molt-to-maturity (Figure I12) were quite similar to the other models for females but were somewhat right-shifted for males-with the consequence that the average mature male would be somewhat larger than that predicted in the other
scenarios. The mean growth curves estimated in scenario 18C2a were among those implying the fastest growth (Figure I1-3).

## iii. Estimated full selection F over time

Estimated time series of fully-selected F (capture rates, not mortality) on males in the directed fishery and bycatch in the snow crab, BBRKC and groundfish fisheries are compared among the model scenarios in Figures 19.1-4.
ii. Estimated male, female, mature male, total and effective mature biomass time series Estimates of population biomass and abundance are shown in Figures I7.2-3. and J.5, J.9, and J.13.
iv. Estimated fishing mortality versus estimated spawning stock biomass

See Section F (Calculation of the OFL; Figure 21).
v. Fit of a stock-recruitment relationship, if feasible.

Not available.

## e. Evaluation of the fit to the data:

i. Graphs of the fits to observed and model-predicted catches

See Appendix I1.
ii. Graphs of model fits to survey numbers

See Appendix I1.
iii. Graphs of model fits to catch proportions by size class

See Appendix I4 for model fits to annual catch proportions by size class.
iv. Graphs of model fits to survey proportions by size class

See Appendix I4 for model fits to annual survey proportions by size class.
v. Marginal distributions for the fits to the compositional data.

See Appendices I2 and I3 for marginal distributions of fits to the compositional data.
vi. Plots of implied versus input effective sample sizes and time-series of implied effective sample sizes.
See Appendices I2 and I3 for plots of implied and input sample sizes. For the most part, the implied effective sample sizes tend to be substantially larger than the input values.
vii. Tables of the RMSEs for the indices (and a comparison with the assumed values for the coefficients of variation assumed for the indices).
RMSEs for fits to various datasets are provided in Tables 24 and 25.
viii. Quantile-quantile ( $q-q$ ) plots and histograms of residuals (to the indices and compositional data) to justify the choices of sampling distributions for the data.
Due to time constraints, quantile-quantile ( $q-q$ ) plots and histograms of residuals were not completed for the assessment.
f. Retrospective and historic analyses (retrospective analyses involve taking the "best" model and truncating the time-series of data on which the assessment is based; a historic analysis involves plotting the results from previous assessments).
i. Retrospective analysis (retrospective bias in base model or models).

Due to time constraints, retrospective analyses were not completed for the assessment.
ii. Historical analysis (plot of actual estimates from current and previous assessments). Due to time constraints, an historical analysis was not completed for the assessment.
g. Uncertainty and sensitivity analyses

MCMC runs were completed for scenario 18C0a to explore model uncertainty. The model was run for a single chain, which was set to run 5 million iterations, keeping results for every $1,000^{\text {th }}$ to reduce serial autocorrelation, with a burn-in period of $1,000,000$ iterations, yielding 4000 samples. Mixing appeared to be sufficient, but this can be difficult to evaluate with only single chains. This run provides empirical posterior distributions for model parameters and selected derived quantities, including OFL-related quantities.

Time constraints did not allow a full exploration of the MCMC results. Summary results for the objective function and OFL-related quantities (Figure 18) indicates that they are reasonably well-behaved and normally-distributed, and do not exhibit unexpected correlation structures (e.g., Fofl and FMSY are expected to be highly correlated). MCMC results for the time trends in recruitment and mature biomass-at-mating are shown in Figure 19.

## F. Calculation of the OFL and ABC

## 1. Status determination and OFL calculation

EBS Tanner crab was elevated to Tier 3 status following acceptance of the TCSAM by the CPT and SSC in 2012. Based upon results from the model, the stock was subsequently declared rebuilt and not overfished. Consequently, EBS Tanner crab is assessed as a Tier 3 stock for status determination and OFL setting.

The (total catch) OFL for 2017/18 was 25.42 thousand $t$ while the total catch mortality was 2.39 thousand t , based on applying mortality rates of 1.000 for retained catch, 0.321 to bycatch in the crab fisheries, and 0.800 to bycatch in the groundfish fisheries to the model-estimated catch by fleet for $2017 / 18$. Therefore overfishing did not occur.

Amendment 24 to the NPFMC fishery management plan (NPFMC 2007) revised the definitions for overfishing for EBS crab stocks. The information provided in this assessment is sufficient to estimate overfishing limits for Tanner crab under Tier 3. The OFL control rule for Tier 3 is (Figure 19):

$$
\begin{aligned}
& B, F_{35 \%}, B_{35 \%} \quad 3 \quad \text { a. } \frac{B}{B_{35 \%^{*}}}>1 \quad F_{O F L}=F_{35 \%} * \\
& \text { b. } \beta<\frac{B}{B_{35 \%} *} \leq 1 \quad F_{O F L}=F^{*}{ }_{35 \%} \frac{\frac{B}{B^{*}{ }_{35 \%}}-\alpha}{1-\alpha} \quad \mathrm{ABC} \leq\left(1-\mathrm{b}_{\mathrm{y}}\right) * \mathrm{OFL} \\
& \text { c. } \frac{B}{B_{35 \%} *} \leq \beta \quad \begin{array}{c}
\text { Directed fishery } F=0 \\
F_{\text {OFL }} \leq \mathrm{F}_{\mathrm{MSY}}{ }^{\dagger}
\end{array}
\end{aligned}
$$

and is based on an estimate of "current" spawning biomass at mating ( $B$ above, taken as the projected MMB at mating in the assessment year) and spawning biomass per recruit (SBPR)-based proxies for $\mathrm{F}_{\mathrm{MSY}}$
and $B_{\text {MSY }}$. In the above equations, $\alpha=0.1$ and $\beta=0.25$. For Tanner crab, the proxy for $F_{M S Y}$ is $F_{35 \%}$, the fishing mortality that reduces the SBPR to $35 \%$ of its value for an unfished stock. Thus, if $\phi(F)$ is the SBPR at fishing mortality $F$, then $\mathrm{F}_{35 \%}$ is the value of fishing mortality that yields $\phi(F)=0.35 \cdot \phi(0)$. The Tier 3 proxy for $\mathrm{B}_{\text {MSY }}$ is $\mathrm{B}_{35 \%}$, the equilibrium biomass achieved when fishing at $\mathrm{F}_{35 \%}$, where $\mathrm{B}_{35 \%}$ is simply $35 \%$ of the unfished stock biomass. Given an estimate of average recruitment, $\bar{R}$, then $B_{35 \%}=$ $0.35 \cdot \bar{R} \cdot \phi(0)$.

Thus Tier 3 status determination and OFL setting for 2018/19 require estimates of $B=\mathrm{MMB}_{2018 / 19}$ (the projected MMB at mating time for the coming year), $\mathrm{F}_{35 \%}$, spawning biomass per recruit in an unfished stock $(\phi(0))$, and $\bar{R}$. Current stock status is determined by the ratio $B / \mathrm{B}_{35 \%}$ for Tier 3 stocks. If the ratio is greater than 1 , then the stock falls into Tier 3 a and $\mathrm{F}_{\mathrm{OFL}}=\mathrm{F}_{\mathrm{MSY}}=\mathrm{F}_{35 \%}$. If the ratio is less than one but greater than $\beta$, then the stock falls into Tier $3 b$ and $\mathrm{F}_{\mathrm{OFL}}$ is reduced from $\mathrm{F}_{35}$. following the descending limb of the control rule (Figure 19). If the ratio is less than $\beta$, then the stock falls into Tier 3c and directed fishing must cease. In addition, if $B$ is less than $1 / 2 \mathrm{~B}_{35 \%}$ (the minimum stock size threshold, MSST), the stock must be declared overfished and a rebuilding plan subsequently developed.

In 2015 , the SOA's Board of Fish, under petition from the commercial Tanner crab fishing industry, changed the minimum preferred size for crab in the area east of $166^{\circ} \mathrm{W}$ longitude in calculations used for setting TACs from 138 mm CW (not including lateral spines) to 125 mm CW . The minimum preferred size in the area west of $166^{\circ} \mathrm{W}$ remained the same ( 125 mm CW ). In assessments before 2017 , an attempt was made to account for retention of slightly $(10 \mathrm{~mm} \mathrm{CW})$ smaller crab in the directed fishery in the western area. Because the preferred size is now the same in both areas, the OFL is calculated assuming both selectivity (as previously) and retention (new) curves are the same in both areas.

In assessments before 2017, a separate "projection model" was used to determine OFL based on results from the assessment model. The estimated coefficient of variation for the estimate of final MMB was used to characterize model uncertainty and provided a calculational basis for determining an empirical probability density function (pdf) for OFL based on sampling final MMB from its assumed pdf. Since the transition to TCSAM02 in 2017, the OFL is calculated within the assessment model based on equilibrium calculations for $\mathrm{F}_{\mathrm{OFL}}$ and projecting the state of the population at the end of the modeled time period one year forward assuming fishing mortality at $\mathrm{F}_{\text {OFL }}$. Using MCMC, one can thus estimate the pdf of OFL (and related quantities of interest) incorporating full model uncertainty.

To calculate the $\mathrm{F}_{\mathrm{OFL}}$, the fishery capture rate for males in the directed fishery is adjusted until the longterm (equilibrium) MMB-at-mating is 35\% of its unfished value. This calculation also depends on the assumed bycatch F's on Tanner crab in the snow crab, BBRKC and groundfish fisheries. As with last year, the average F over the last 5 years for each of the bycatch fisheries is used in these calculations (in previous years, a different approach was used to determine the F to use for the snow crab fishery - see e.g., Stockhausen, 2016).

Selectivity curves in the bycatch fisheries were set using the average curves over the last 5 years for each fishery, the same approach as in previous assessments (Stockhausen 2017).

The determination of $\mathrm{B}_{\mathrm{MSY}}=\mathrm{B}_{35 \%}$ for Tanner crab depends on the selection of an appropriate time period over which to calculate average recruitment $(\bar{R})$. Following discussion in 2012 and 2013, the SSC endorsed an averaging period of 1982+. This issue was revisited at the May 2018 CPT meeting with regard to the final year to be included in the calculation, but no definitive were made. Starting the average recruitment period in 1982 is consistent with a 5-6 year recruitment lag from 1976/77, when a wellknown climate regime shift occurred in the EBS (Rodionov and Overland, 2005) that may have affected stock productivity. The value of $\bar{R}$ for this period from MCMC runs of the author's preferred model is 198.99 million. The estimates of average recruitment are reasonably similar between the 2017 assessment
model (214 million) and the author's preferred model (Table 38). The value of $\mathrm{B}_{\mathrm{MSY}}=\mathrm{B}_{35 \%}$ for $\bar{R}$ is 21.87 thousand t , which is smaller than that from the 2017 assessment ( 29 thousand t ).

Once Fofl is determined using the control rule (Figure 19), the (total catch) OFL can be calculated based on projecting the population forward one year assuming that $F=$ Fofl. In the absence of uncertainty, the OFL would then be the predicted total catch taken when fishing at $F=\mathrm{F}_{\text {OFL }}$. When uncertainty (e.g. assessment uncertainty, variability in future recruitment) is taken into account, the OFL is taken as the median total catch when fishing at $F=$ Fofl.

The total catch (biomass), including all bycatch of both sexes from all fisheries, was estimated using

$$
C=\sum_{f} \sum_{x} \sum_{z} \frac{F_{f, x, z}}{F_{,, x, Z}} \cdot\left(1-e^{-F_{,, x, z}}\right) \cdot w_{x, z} \cdot\left[e^{-M_{x} \cdot \delta t} \cdot N_{x, Z}\right]
$$

where $C$ is total catch (biomass), $F_{f, x, z}$ is the fishing mortality in fishery $f$ on crab in size bin $z$ by sex $(x)$, $F_{,, x, z}=\sum_{f} F_{f, x, Z}$ is the total fishing mortality by sex on crab in size bin $z, w_{x, z}$ is the mean weight of crab in size bin $z$ by sex, $M_{x}$ is the sex-specific rate of natural mortality, $\delta t$ is the time from July 1 to the time of the fishery ( 0.625 yr ), and $N_{x, z}$ is the numbers by sex in size bin $z$ on July 1,2018 as estimated by the assessment model.

Assessment model uncertainty was included in the calculation of OFL using MCMC. Conceptually, a random draw from the assessment model's joint posterior distribution for the estimated parameters was taken, and the $\bar{R}, \mathrm{~B}_{0}, \mathrm{~F}_{\text {MSY }}, \mathrm{B}_{\text {MSY }}, \mathrm{F}_{\text {OFL }}$, OFL, and "current" MMB for 2018/19 were calculated based on resulting model parameter values. This would be repeated a large number of times to approximate the distribution of OFL given the full model uncertainty. In practice, a single (due to time constraints) chain of 5 million MCMC steps was generated, with the OFL and associated quantities calculated at each step. The chain was initialized from the converged model state using a "burn in" of 1,000,000 steps and subsequently thinned by a factor of 1,000 to reduce serial autocorrelation in the MCMC sampling. This resulted in about $4,000 \mathrm{MCMC}$ samples with which to characterize the distribution of the OFL. The median value of this distribution was taken as the OFL for 2018/19. Thus, the OFL for 2018/19 from the author's preferred model (Model 18C2a) is 16.46 thousand $\mathbf{t}$ (Figure 20).

The $\mathrm{B}_{\text {MSY }}$ proxy, $\mathrm{B}_{35 \%}$, from the author's preferred model is 21.87 thousand t , so MSST $=0.5 \mathrm{~B}_{\text {MSY }}=$ 10.93 thousand t . Because current projected $B=23.53$ thousand $\mathrm{t}>$ MSST, the stock is not overfished. The population state (directed F vs. MMB) is plotted for each year from 1965/66-2017/18 in Figure 21 against the Tier 3 harvest control rule.

## 2. ABC calculation

Amendments 38 and 39 to the Fishery Management Plan (NPFMC 2010) established methods for the Council to set Annual Catch Limits (ACLs). The Magnuson-Stevens Act requires that ACLs be established based upon an acceptable biological catch (ABC) control rule that accounts for scientific uncertainty in the OFL such that $\mathrm{ACL}=\mathrm{ABC}$ and the total allowable catch (TAC) and guideline harvest levels (GHLs) be set below the ABC so as not to exceed the ACL. ABCs must be recommended annually by the Council's SSC.

Two methods for establishing the ABC control rule are: 1) a constant buffer where the ABC is set by applying a multiplier to the OFL to meet a specified buffer below the OFL; and 2) a variable buffer where the ABC is set based on a specified percentile $\left(\mathrm{P}^{*}\right)$ of the distribution of the OFL that accounts for uncertainty in the OFL. $\mathrm{P}^{*}$ is the probability that ABC would exceed the OFL and overfishing occur. In 2010, the NPFMC prescribed that ABCs for BSAI crab stocks be established at $\mathrm{P}^{*}=0.49$ (following Method 2). Thus, annual ACL=ABC levels should be established such that the risk of ovefishing,
$\mathrm{P}[\mathrm{ABC}>\mathrm{OFL}]$, is $49 \%$. In 2014, however, the SSC adopted a buffer of $20 \%$ on OFL for the Tanner crab stock for calculating ABC. Here, ABCs are provided based on both methods.

For the author's preferred scenario, 18 C 2 a , the $\mathrm{P}^{*} \mathrm{ABC}\left(\mathrm{ABC}_{\max }\right)$ is 16.44 thousand t while the $20 \%$ Buffer ABC is 13.17 thousand $t$. The author remains concerned that the OFL calculation, based on $\mathrm{F}_{35 \%}$ as a proxy for $\mathrm{F}_{\mathrm{MSY}}$, is overly optimistic regarding the actual productivity of the stock. Fishery-related mortality similar to the P* ABC level has occurred only in the latter half of the 1970s and in 1992/93, coincident with collapses in stock biomass to low levels. This suggests that $\mathrm{F}_{35 \%}$ may not be a realistic proxy for $\mathrm{F}_{\text {MSY }}$ and/or that MMB may not be a good proxy for reproductive success, as are currently assumed for this stock. Given this uncertainty concerning the stock, the author recommends using the $\mathbf{2 0 \%}$ buffer previously adopted by the SSC for this stock to calculate ABC. Consequently, the author's recommended ABC is $\mathbf{1 3 . 1 7}$ thousand $\mathbf{t}$.

## G. Rebuilding Analyses

Tanner crab is not currently under a rebuilding plan. Consequently no rebuilding analyses were conducted.

## H. Data Gaps and Research Priorities

Information on growth-per-molt has been collected in the EBS on Tanner crab and incorporated into the assessment. More data regarding temperature-dependent effects on molting frequency would be helpful to assess potential impacts of the EBS cold pool on the stock. Information on temperature-dependent changes in crab movement and survey catchability would also be of value. In addition, it would be extremely worthwhile to develop a "better" index of reproductive potential than MMB that can be calculated in the assessment model and to revisit the issue of MSY proxies for this stock.

The characterization of fisheries in the assessment model needs to be carefully reconsidered. How, and whether or not, the differences in the directed fishery in areas east and west $166^{\circ} \mathrm{W}$ longitude should be explicitly represented in the assessment model should be addressed. The question of whether or not bycatch in the groundfish fisheries should be split into pot- and trawl-related components should be revisited. Also, the appropriate weight for male maturity ogives based on NMFS survey data in the model likelihood needs to be explored.

With the implementation of TCSAM02, several research avenues can be explored much more efficiently: 1) time-varying growth; 2 ) decomposing the currently "lumped" directed fishery into its eastern and western components, and 3 ) incorporating the BSFRF surveys into the assessment. Development of a fully-Gmacs version of the Tanner crab model will also begin.

## I. Ecosystem Considerations

Mature male biomass is currently used as the "currency" of Tanner crab spawning biomass for assessment purposes. However, its relationship to stock-level rates of egg production, perhaps an ideal measure of stock-level reproductive capacity, is unclear. Thus, use of MMB to reflect Tanner crab reproductive potential may be misleading as to stock health. Nor is it likely that mature female biomass has a clear relationship to annual egg production. For Tanner crab, the fraction of barren mature females by shell condition appears to vary on a decadal time scale (Rugolo and Turnock, 2012), suggesting a potential climatic driver.

## 1. Ecosystem Effects on Stock

Time series trends in prey availability or abundance are generally unknown for Tanner crab because typical survey gear is not quantitative for Tanner crab prey. On the other hand, Pacific cod (Gadus macrocephalus) is thought to account for a substantial fraction of annual mortality on Tanner crab (Aydin et al., 2007). Total P. cod biomass is estimated to have been slowly declining from 1990 to 2008, during
the time frame of a collapse in the Tanner crab stock, but has been increasing rather rapidly since 2008 (Thompson and Lauth, 2012). This suggests that the rates of "natural mortality" used in the stock assessment for the period post-1980 may be underestimates (and increasingly biased low if the trend in P. cod abundance continues). This trend is definitely one of potential concern.

## 2. Effects of Tanner crab fishery on ecosystem

Potential effects of the Tanner crab fishery on the ecosystem are considered in the following table:

| Effects of Tanner crab fishery on ecosystem |  |  |  |
| :---: | :---: | :---: | :---: |
| Indicator | Observation | Interpretation | Evaluation |
| Fishery contribution to bycatch |  |  |  |
| Prohibited species | salmon are unlikely to be trapped inside a pot when it is pulled, although halibut can be | unlikely to have substantial effects at the stock level | minimal to none |
| Forage (including herring, Atka mackerel, cod and pollock) | Forage fish are unlikely to be trapped inside a pot when it is pulled | unlikely to have substantial effects | minimal to none |
| HAPC biota | crab pots have a very small footprint on the bottom | unlikely to be having substantial effects postrationalization | minimal to none |
| Marine mammals and birds | crab pots are unlikely to attract birds given the depths at which they are fished | unlikely to have substantial effects | minimal to none |
| Sensitive non-target species | Non-targets are unlikely to be trapped in crab pot gear in substantial numbers | unlikely to have substantial effects | minimal to none |
| Fishery concentration in space and time | substantially reduced in time following rationalization of the fishery | unlikely to be having substantial effects | probably of little concern |
| Fishery effects on amount of large size target fish | Fishery selectively removes large males | May impact stock reproductive potential as large males can mate with a wider range of females | possible concern |
| Fishery contribution to discards and offal production | discarded crab suffer some mortality | May impact female spawning biomass and numbers recruiting to the fishery | possible concern |
| Fishery effects on age-atmaturity and fecundity | none | unknown | possible concern |

Table 36. Comparison of estimates of recruitment (in millions) from the 2017 assessment model (17AM) and the author's preferred model (18C2a). ..... 81
Table 37. Comparison of exploitation rates (i.e., catch divided by biomass) from the 2017 assessment model 17AM) and the author's preferred model (18C2a). ..... 82
Table 38. Values required to determine Tier level and OFL for the models considered here. These valuesare presented only to illustrate the effect of incremental changes in the model scenarios. Results from theauthor's preferred model 18C2a) are highlighted in green.83

## Figure captions

Figure 1. Eastern Bering Sea District of Tanner crab Registration Area J including sub-districts and sections (from Bowers et al. 2008) ..... 84
Figure 2. Upper: retained catch (males, 1000's $t$ ) in the directed fisheries (US pot fishery [green bars],Russian tangle net fishery [red bars], and Japanese tangle net fisheries [blue bars]) for Tanner crab since1965/66. Lower: Retained catch (males, 1000's t) in directed fishery since 2001/02. The directed fisherywas closed from 1996/97 to 2004/05, from 2010/11 to 2012/13, and in 2016/1785
Figure 3. Upper: total catch (retained + discards) of Tanner crab (males and females, 1000's t) in the directed Tanner crab, snow crab, Bristol Bay red king crab, and groundfish fisheries. Bycatch reportingbegan in 1973 for the groundfish fisheries and in 1992 for the crab fisheries. Lower: detail since 2001. . 86

Table 2. Retained catch (males) in the US domestic pot fishery. Information from the Community Development Quota (CDQ) fisheries is included in the table for fishery years 2005/06 to the present. Number of crabs caught and harvest includes deadloss. The "Fishery Year" YYYY/YY+1 runs from July 1, YYYY to June 30, YYYY+1. The ADFG year (in parentheses, if different from the "Fishery Year") indicates the year ADFG assigned to the fishery season in compiled reports.

| year <br> (ADFG year) | Total <br> Crab <br> (no.) | Total Harvest (lbs) | GHL/TAC (millions lbs) | Vessels (no.) | Season |

## Figures

Figure 1. Eastern Bering Sea District of Tanner crab Registration Area J including sub-districts and sections (from Bowers et al. 2008).

Figure 2. Upper: retained catch (males, 1000's t) in the directed fisheries (US pot fishery [green bars], Russian tangle net fishery [red bars], and Japanese tangle net fisheries [blue bars]) for Tanner crab since 1965/66. Lower: Retained catch (males, 1000's t) in directed fishery since 2001/02. The directed fishery was closed from 1996/97 to 2004/05, from 2010/11 to 2012/13, and in 2016/17.

Figure 3. Upper: total catch (retained + discards) of Tanner crab (males and females, 1000's $t$ ) in the directed Tanner crab, snow crab, Bristol Bay red king crab, and groundfish fisheries. Bycatch reporting began in 1973 for the groundfish fisheries and in 1992 for the crab fisheries. Lower: detail since 2001.

Figure 4. Size-weight relationships developed from NMFS EBS summer trawl survey data.

Figure 5. Assumed size distribution for recruits entering the population.

Figure 6. Fits to mature survey biomass for scenarios 17AM and 17AMu. Points: input data; lines: model estimates.

Figure 7. Fits to retained catch biomass (upper) and total male catch biomass (lower) for the directed fishery for scenarios 17AM and 17AMu. Points: input data; lines: model estimates.

Figure 8. Fits to total male bycatch biomass for the snow crab fishery for scenarios 17 AM and 17 AMu . Points: input data; lines: model estimates.

Figure 9. Estimated survey catchabilities (left) and capture probabilities (catchability x selectivity; right) for scenarios 17AM and 17AMu.

Figure 10. Estimated recruitment for scenarios 17AM and 17AMu.

Figure 11. Estimated mature biomass for scenarios 17AM and 17AMu.

Figure 12. Fits to mature survey biomass for scenarios 17 AMu and 18A. Points: input data; lines: model estimates.

Figure 13. Fits to retained catch biomass (upper) and total male catch biomass (lower) for the directed fishery for scenarios 17AMu and 18A. Points: input data; lines: model estimates.

Figure 14. Fits to total male bycatch biomass for the snow crab fishery for scenarios 17 AMu and 17 AMu . Points: input data; lines: model estimates.

Figure 15. Estimated survey catchabilities (left) and capture probabilities (catchability x selectivity; right) for scenarios 17AMu and 18A.

Figure 16. Estimated recruitment for scenarios 17AMu and 18A.

Figure 17. Estimated mature biomass for scenarios 17 AMu and 18A.

Figure 18. MCMC results from scenario 18 C 2 a , the author's preferred model, for OFL-related quantities.

Figure 19. MCMC results from scenario 18C2a, the author's preferred model, for recruitment (upper plot) and mature biomass-at-mating (lower plot; males in red, females in green).

Figure 20. The $\mathrm{F}_{\text {OFL }}$ harvest control rule.

Figure 21. The OFL and ABC from the author's preferred model, scenario 18C2a.

Figure 22. Quad plot for the author's preferred model, scenario B2b.

# Appendix A: Retained Catch Data from ADFG for the Tanner Crab Assessment 

William Stockhausen

21 August, 2018

## Contents

Introduction ..... 2
Retained catch abundance and biomass ..... 2
Size compositions ..... 11
List of Tables
1 Retained catch of Tanner crab since 2005, by fishery. TCF: Tanner crab fisheries, SCF: snow crab fishery, RKF: BBRKC fishery ..... 6
2 All retained catch of Tanner crab since 2005. ..... 10
List of Figures
1 Retained Tanner crab catch, in millions of crab. TCF: Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery. ..... 3
2 Retained Tanner crab catch, in millions of pounds. TCF: Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery. ..... 4
3 Retained Tanner crab catch, in 1000's t. TCF: Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery ..... 5

## Introduction

This report calculates time series of retained catch abundance and biomass of Tanner crab from fish ticket data, as well as retained catch size compositions from observer "dockside" sampling. Although Tanner crab are incidentally retained in the BBRKC and snow crab fisheries, this incidental catch is a small fraction of the retained catch in the directed fisheries and is currently, as a model simplification, included in the retained catch for the directed fisheries in the assessment model.

## Retained catch abundance and biomass

Time series of retained catch abundance and biomass are calculated in this section. First, the retained catch ispresented categorized by the fishery in which it occurs. Then it is presented as it occurs in the assessment model, where incidentally-retained catch in the snow crab and BRKC fisheries is lumped in with that in the directed fisheries.

## Introduction

This report calculates total catch abundance and biomass, as well as total catch size compositions, of Tanner crab in the crab fisheries from "at sea" observer sampling.

## Total catch abundance and biomass

Time series of total catch abundance and biomass, based on ADFG "at sea" observer sampling in the crab fisheries, are calculated in this section.

Figure 1: Total Tanner crab catch, in millions of crab. TCF: directed Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery.

Figure 2: Total Tanner crab catch, in 1000's t. TCF: directed Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery.

Table 1: Total catch biomass of Tanner crab, by fishery. TCF: directed Tanner crab fisheries, SCF: snow crab fishery, RKF: BBRKC fishery.

# Appendix C: Effort in the Crab Fisheries: A Comparison of Two Datasets from ADFG 

## Contents

William Stockhausen

01 September, 2018

## List of Figures

1 Fishery effort from 1990+ dataset. TCF: Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery.4

2 Fishery effort from 1990+ dataset, only 2005+ is shown. TCF: Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery.
3 Fishery effort from 2005+ dataset. TCF: Tanner crab fisheries; SCF: snow crab fishery; RKF: BBRKC fishery.

## Introduction

This report calculates annual fishing effort by crab fishery as the total number of potlifts conducted for each target species (Tanner crab, snow crab, and red king crab in Bristol Bay) across the EBS. Two datasets were provided by ADFG, one starting in 1990 that separately compiled effort east and west of $166^{\circ} \mathrm{W}$ longitude for all three target species and the second starting in 2005 that separately compiled effort east/west of $166^{\circ} \mathrm{W}$ only for the directed Tanner crab fisheries. Here, effort is summed annually to total effort across the EBS for each target species. As indicated in Table 1 below, the two effort datasets are not always consistent with one another. The first dataset is consistent with effor data previously used in the Tanner crab assessment.

## Introduction

This paper documents the calculations for the annual abundance and biomass time series and the sex-specific size compositions for Tanner crab bycatch in the groundfish fisheries used in the Tanner crab stock assessment model for 1991-2017. Briefly, total bycatch estimates were obtained from AKFIN for 1991-2008 from the NMFS Alaska Regional Office's (AKRO) Catch Accounting System/Blend database (CAS; Cahalan et al., 2009) and for 2009 to the present from the AKRO's Catch-in-Areas database (CIA). Annual sampling data for size frequencies of Tanner crab bycatch in the EBS groundfish fisheries was extracted from the NORPAC observer database (via AKFIN) by sex, gear ("trawl" and "fixed"), ADFG stat area and NMFS reporting area. These observed size frequency data were then scaled to total estimated bycatch size compositions using year/gear/area expansion factors based on the annual total bycatch estimates from the CAS and CIA database.
Sex-specific size compositions for Tanner crab bycatch in the groundfish fisheries during 1973-1990 are also incorporated in the assessment model. These size compositions are based on data from the former "joint venture"" and foreign fishing fleets, and remain unchanged from the previous assessment.

Figure 3: Bycatch of Tanner crab in the groundfish fisheries, by target type.

## Estimated total catch by target type (2009/10-2017/18)

Table 2: Bycatch of Tanner crab in the groundfish fisheries, by target type. Biomass is in metric tons, numbers in 1000's of crab. Targets with less than 10 kg bycatch have been dropped.

Figure 4: Sample sizes from observer sampling for Tanner crab ( $>24 \mathrm{~mm}$ CW) bycatch size frequencies in the groundfish fisheries.

## Size frequencies from observer sampling

Observers sampled Tanner crab bycatch in the groundfish fisheries to obtain sex and size information starting in 1985. Observer coverage varied by year across target fisheries and gear types, hence "raw" size frequencies are not necessarily directly comparable across these categories. Here, I assume it is valid to aggregate observations across target fisheries and to categorize gear types as "fixed" (longline and pot gear) and "trawl" (pelagic, non-pelagic, and unspecified trawl gear) to obtain annual sex- and gear-specific observed size frequencies by NMFS reporting area.

## Sample sizes

Raw size frequencies

Figure 5: Raw (unscaled) size frequencies by 1-mm size bin from observer sampling for Tanner crab bycatch in the groundfish fisheries.

Figure 6: Raw (unscaled) size frequencies by 1-mm size bin from observer sampling for Tanner crab bycatch in the groundfish fisheries.

Figure 7: Raw (unscaled) size frequencies by 1-mm size bin from observer sampling for Tanner crab bycatch in the groundfish fisheries.

Figure 8: Raw (unscaled) size frequencies by 1-mm size bin from observer sampling for Tanner crab bycatch in the groundfish fisheries.

Expansion factors

Figure 9: Expansion factors from observed size frequencies to total bycatch, by gear type and reporting area.

Table 3: Observed bycatch numbers, expanded numbers, ans expansion factors from observed size frequencies to total bycatch, by gear type and reporting area.

| area | year | fixed |  |  | trawl |  |  |

## Spatial patterns of bycatch

Spatial patterns of Tanner crab bycatch in the groundfish fisheries, by ADFG stat area for 2009-2017, are illustrated by gear type in Figures 20-21 below. Bycatch less than 0.1 t in a stat area is not shown.

Figure 19: Bycatch of Tanner crab, by ADFG stat area, in the groundfish fisheries during 2009/10.

## Introduction

This report calculates NMFS survey data time series (aggregate abundance, mature biomass and size compositions) for Tanner crab based on CRABHAUL files and a haul/station strata file downloaded from AKFIN.

The survey data were processed using the following parameters:
Table 1: Parameters used to process crab haul data.

|  | Quantity | Value |
| :---: | :---: | :---: |
| 1 | min size (mm CW) | 25 |
| 2 | max size (mm CW) | 185 |
| 3 | bin size (mm CW) | 5 |
| 4 | strata type | 2015 |
| 5 | haul types | all |

## Annual survey abundance and biomass

Annual survey abundance and biomass for Tanner crab for the EBS and the areas east and west of $166^{\circ} \mathrm{W}$ longitude were calculated from the survey haul data as if the survey were conducted using a random-stratified sampling design (it uses a fixed grid), with survey strata defined for the Pribilof Islands high density sampling area, the St. Matthew Island high density sampling area, the standard-density sampling area west of $166^{\circ} \mathrm{W}$ longitude, and the standard-density area east of $166^{\circ} \mathrm{W}$ longitude. Abundance and biomass estimates from the four strata were then aggregated appropriately to the areas east and west of $166^{\circ} \mathrm{W}$ and to the entire EBS.

## By sex

The following plots illustrate time series trends in Tanner crab survey abundance and biomass by sex and area.

Figure 1: Tanner crab biomass in the NMFS EBS trawl survey, by sex and area.

Figure 2: Tanner crab biomass in the NMFS EBS trawl survey, by sex and area, since 2001.

Figure 3: Tanner crab abundance in the NMFS EBS trawl survey, by sex and area.

Figure 4: Tanner crab abundance in the NMFS EBS trawl survey, by sex and area, since 2001.

## By sex and maturity state

The following plots illustrate the time series trends for Tanner crab survey abundance and biomass by sex, maturity state, and area.

Figure 5: Tanner crab biomass in the NMFS EBS trawl survey, by sex, maturity state and area.

Figure 6: Tanner crab biomass in the NMFS EBS trawl survey, by sex, maturity state and area, since 2001.

Figure 7: Tanner crab abundance in the NMFS EBS trawl survey, by sex, maturity state and area.

Figure 8: Tanner crab abundance in the NMFS EBS trawl survey, by sex, maturity state and area, since 2001.

## Time series survey trends in industry preferred-sized males

The Tanner crab fishery is managed separately east and west of $166^{\circ} \mathrm{W}$ longitude, and separate TACs are set for each area. Abundance and biomass trends from the NMFS EBS bottom trawl survey are shown in subsequent figures for the current industry-preferred size of legal crab (i.e., $\geq$ 125 mm CW).

Figure 9: Legal male Tanner crab biomass in the NMFS EBS trawl survey, by area.

Figure 10: Industry-preferred male Tanner crab biomass in the NMFS EBS trawl survey, by area, since 2001.

Figure 11: Legal male Tanner crab abundance in the NMFS EBS trawl survey, by area.

Figure 12: Industry-preferred male Tanner crab abundance in the NMFS EBS trawl survey, by area, since 2001.

## Size compositions

Annual size compositions for Tanner crab in the NMFS EBS trawl survey were calculated by sex, maturity state, shell condition, and 5 mm size (carapace width) bin, excluding individuals with sizes $<25 \mathrm{~mm}$ CW and accumulating individuals in the last size bin (180-185 mm CW) for sizes $>185$ mm CW. Individuals classified in the survey as "immature, old shell" crab were assumed to really be "immature, new shell"" crab and were re-classified as such.

By sex

Figure 13: Annual size compositions for Tanner crab in the NMFS EBS trawl survey, by sex and area.

By shell condition for males

## Males

Figure 14: Annual size compositions for male Tanner crab in the NMFS EBS trawl survey, by shell condition and area.

By maturity state for females

Figure 15: Annual size compositions for female Tanner crab in the NMFS EBS trawl survey, by shell condition and area.

## Sample sizes

The following tables summarize sample sizes for Tanner crab in the NMFS EBS bottom trawl survey.

Table 2: Observed numbers of Tanner crab in the annual NMFS EBS bottom trawl survey, by sex, maturity state, and shell condition.

| year | female |  |  |  | male unknown |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | immature |  | mature |  |  |  |
|  | new shell | old shell | new shell | old shell | new shell | old shell |

Introduction
Basemap
Survey CPUE

## Introduction

This report creates a time series of maps of Tanner crab CPUE and bottom temperature from the NMFS EBS bottom trawl survey.

## Basemap

The following figure illustrates the base map for subsequent maps of bottom temperature and survey CPUE.

Figure 1: Basemap for future maps, with EBS bathymetry (blue lines) and the NMFS EBS bottom trawl survey station grid.

## Survey CPUE

The following maps present survey CPUE (in biomass) for components of the Tanner crab stock superimposed on bottom temperature at the time of the survey for each year of the NMFS bottom trawl survey.

Figure 2: Tanner crab CPUE (biomass) from the 2012 NMFS EBS bottom trawl survey.

# Appendix G: <br> Male Maturity Data From the NMFS Survey 

William Stockhausen

26 February, 2018

## Chela height data and maturity state

Individuals can be classified as functionally "mature" or "immature" on the basis of the ratio of chela height (CH) to carapace width (CW). For example, based on a cutpoint analysis to separate two mixed distributions of Tanner crab collected in Glacier Bay in the Gulf of Alaska, Tamone et al. (2007) classified crab exhibiting a ratio > 0.18 as functionally " mature" whereas crab exhibiting a ratio $<0.18$ were classified as functionally "immature".

Chela height data from the NMFS EBS bottom trawl survey are available for male Tanner crab for specific years for surveys from 1975 to 2017 . Robert Foy (AFSC) used a cutpoint analysis on 10-mm CW size bins to classify individual male Tanner crab as immature or mature based on their $\mathrm{CH} / \mathrm{CW}$ ratio. "Raw"" maturity ogives were then calculated for each year in which chela height data were collected as the ratio of the number of mature to total new shell crab by size bin. The raw ogives were calculated using both $1-\mathrm{mm}$ and $5-\mathrm{mm}$ size bins, and fit using with logistic curves using the glm package in $R$ with binomial family and logit link. The resulting raw and fitted maturity ogives are shown in the following plots.

Figure 1: Tanner crab molt increment data, by region and sex.

## Tanner crab growth data

Figure 1 shows molt increment data collected from crab near Kodiak Island in the Gulf of Alaska and in the eastern Bering Sea (EBS). THe Kodiak data was collected over a $20+$ year period during opportunistic surveys and caged grow-out experiments. The EBS data was collected in 2014, 2015, and 2016 through cooperative research conducted by the AFSC/NMFS and the Bering Sea Research Foundation (BSFRF).

## Mean growth

Sex-specific parameters for post-molt size as a power function of pre-molt size ( $z_{\text {post }}=e^{a} \cdot z_{\text {pre }}{ }^{b}$ ) were estimated in R using the glm function from the EBS data on the log-scale using the regression formula $\ln \left[z_{p o s t}\right]=a+b \cdot \ln \left[z_{p r e}\right]$. The resulting estimates

Table 1: Estimated growth parameters for the EBS molt increment data with post-molt size as a power lae of pre-molt size..

| parameter | males | females |
| :---: | :---: | :---: |
| a | 0.2708370 | 0.6106653 |
| b | 0.9922623 | 0.8975509 |

Sex-specific parameters from the 2016 assessment model reflecting estimated mean growth are listed in Table 2, where $z_{\text {post }}=e^{a} \cdot z_{\text {pre }}{ }^{b}$.

Table 2: 2016 assessment model mean growth parameters.

| parameter | males | females |
| :---: | :---: | :---: |
| a | 0.4220295 | 0.6999999 |
| b | 0.9721004 | 0.8850577 |

Growth parameters estimated from the Kodiak data, used as prior mean values for parameters in the assessment model are listed in Table 3.
Table 3: Growth parameters based on Kodiak data, used as prior means for parameters in the assessment model.

| parameter | males | females |
| :---: | :---: | :---: |
| a | 0.437941 | 0.5656024 |
| b | 0.948700 | 0.9132661 |

Figure 2: Tanner crab growth data, by region and sex. Colored lines indicate mean growth, by sex, as determined by the assessment model.

## Comparison with the 2016 assessment model

The 2016 assessment model estimated mean growth parameters from size composition data. Priors were placed on the growth parameters based on a previous analysis by Rugolo and Turnock of molt increment data from Kodiak Island in the Gulf of Alaska. The estimated mean growth curves from the assessment over-predict post-molt size at larger pre-molt sizes for both males and females. The molt increment data from the EBS does not appear to be radically different from that collected at Kodiak. In the current assessment, only the EBS data will be included to fit.

# Appendix I1: <br> Model Comparisons: Aggregated Catch Data for the " 18 " Scenarios 

William Stockhausen

Model fits to "other" data 1
Growth data 2
Maturity data 5

## Model fits to "other" data

Fits to growth data and male maturity datasets by the model(s) are presented in this section. Not all of the fits presented are necessarily included in the parameter optimization for each model; some fits for a particular model may be included for comparison purposes with other models which include those data in their optimization. The reader should consult the main assessment document to determine which fits are included in the optimization for any particular model.

## Growth data

Figure 1: Model fits to EBS.

## EBS

Figure 2: Negative log-likelihood values for fits to EBS.

Figure 3: Z-scores for fits to EBS.

## Maturity data

In the male maturity dataset used in this assessment, a number of male crab less than 60 mm CW were classified as mature based on their chela height-to-carapace width ratios. For the purposes of fitting the data, these crab were assumed to be misclassified and to actually be immature. Consequently, data from size bins less than 60 mm CW, although shown in the following plots comparing model predictions to observations, were not included in the likelihood used for model optimization and are not shown in the NLL and z-score plots.

## Appendix K: <br> Description of the Tanner Crab Stock Assessment Model (ver. 2)

## Introduction

The computer code used in the 2016 Tanner crab stock assessment (Stockhausen, 2016), referred to here as "TCSAM2013" (i.e., an acronym for Tanner Crab Stock Assessment Model, 2013), evolved directly from the assessment model code developed by Rugolo and Turnock (2011, 2012a) used in the 2012 stock assessment (Rugolo and Turnock, 2012b), as rewritten and revised by Stockhausen for the 2013 and subsequent stock assessments (Stockhausen et al., 2013; Stockhausen, 2014; Stockhausen, 2015; Stockhausen, 2016). TCSAM2013, no longer used for assessments, was an integrated assessment model that estimated model parameters in a maximum likelihood framework using AD Model Builder C++ libraries (Fournier et al., 2012) for automatic differentiation to fit to time series of survey (fisheryindependent) biomass and size compositions, retained catch biomass and size compositions in the directed fishery, and catch biomass and size compositions in several fisheries that take Tanner crab as bycatch. The computer code for the TCSAM2013 is available on GitHub (the 2016 assessment model version is on the "2016AssessmentModel" branch). While a number of model options could be configured "on-the-fly" using a control file, assessment models developed using the TCSAM2013 computer code were constrained in a number of ways, including the number of directed fisheries (1) and bycatch fisheries (3) that can be accommodated, the type of surveys that can accommodated (1), and the number and type of time blocks that are defined for model parameters (most are hard-wired in the code). Additionally, status determination and overfishing limit (OFL) calculations required a separate "projection model" code to be run separately using a results file from a successful TCSAM2013 model run.

The "TCSAM02" (Tanner Crab Stock Assessment Model, version 2) modeling framework was developed "from scratch" to eliminate many of the constraints imposed on potential future assessment models by TCSAM2013. Like TCSAM2013, TCSAM02 uses AD Model Builder libraries as the basis for model optimization using a maximum likelihood (or Bayesian) approach. The model code for TCSAM02 is available on GitHub (the current development branch is "After201705CPT"). TCSAM02 was first used for the Tanner crab assessment in 2017 (Stockhausen, 2017) and will be used until a transition is made to Gmacs (the $\underline{\text { Generalized }} \underline{\text { Model for Alaska } \underline{\text { Crab }} \underline{\text { Stocks). }} \text {. Gmacs is intended to be used for all crab stock }}$ assessments conducted for the North Pacific Fisheries Management Council (NPFMC), including both lithodid (king crab) and Chionoecetes (Tanner and snow crab) stocks, while TCSAM02 is specific to Chionoecetes biology (i.e., terminal molt)..

TCSAM02 is referred to here as a "modeling framework" because, somewhat similar to Stock Synthesis (Methot and Wetzel, 2013), model structure and parameters are defined "on-the-fly" using control filesrather than editing and re-compiling the underlying code. In particular, the number of fisheries and surveys, as well as their associated data types (abundance, biomass, and /or size compositions) and the number and types of time blocks defined for every model parameter, are defined using control files in TCSAM02 and have not been pre-determined. Priors can be placed on any model parameter. New data types (e.g., growth data) can also be included in the model optimization that could not be fit with TCSAM2013. Additionally, status determination and OFL calculations can be done directly within a TCSAM02 model run, rather having to run a separate "projection model".

## Model Description

## A. General population dynamics

TCSAM02 is a stage/size-based population dynamics model. Population abundance at the start (July 1) of year $y$ in the model, $n_{y, x, m, s, z}$, is characterized by sex $x$ (male, female), maturity state $m$ (immature, mature), shell condition $s$ (new shell, old shell), and size $z$ (carapace width, CW). Changes in abundance due to natural mortality, molting and growth, maturation, shell aging, fishing mortality and recruitment are tracked on an annual basis. Because the principal crab fisheries occur during the winter, the model year runs from July 1 to June 30 of the following calendar year.

The order of calculation steps to project population abundance from year $y$ to $y+1$ depends on the assumed timing of the fisheries $\left(\delta t_{y}^{F}\right)$ relative to molting/growth/mating $\left(\delta t_{y}^{m}\right)$ in year $y$. The steps when the fisheries occur before molting/growth/mating ( $\delta t_{y}^{F} \leq \delta t_{y}^{m}$ ) are outlined below first (Steps A1.1-A1.4), followed by the steps when molting/growth/mating occurs after the fisheries ( $\delta t_{y}^{m}<\delta t_{y}^{F}$;

Fig. 1. Timing of annual events in TCSAM02 when fisheries occur before molting/growth/mating. Steps A2.1-A2.4).

## A1. Calculation sequence when $\boldsymbol{\delta} \boldsymbol{t}_{\boldsymbol{y}}^{\boldsymbol{F}} \leq \boldsymbol{\delta} \boldsymbol{t}_{\boldsymbol{y}}^{\boldsymbol{m}}$

## Step A1.1: Survival prior to fisheries

Natural mortality is applied to the population from the start of the model year (July 1) until just prior to prosecution of pulse fisheries for year $y$ at $\delta t_{y}^{F}$. The numbers surviving to $\delta t_{y}^{F}$ in year $y$ are given by:

| $n_{y, x, m, s, z}^{1}=e^{-M_{y, x, m, s, z} \cdot \delta t_{y}^{F}} \cdot n_{y, x, m, s, z}$ | A1.1 |
| :--- | :---: |

where $M$ represents the annual rate of natural mortality in year $y$ on crab classified as $x, m, s, z$.
Step A1.2: Prosecution of the fisheries
The directed and bycatch fisheries are modeled as simultaneous pulse fisheries occurring at $\delta t_{y}^{F}$ in year $y$. The numbers that remain after the fisheries are prosecuted are given by:

| $n_{y, x, m, s, z}^{2}=e^{-F_{y, x, m, s, z}^{T} \cdot n_{y, x, m, s, z}^{1}}$ | A1.2 |
| :--- | :---: |

where $F_{y, x, m, s, z}^{T}$ represents the total fishing mortality (over all fisheries) on crab classified as $x, m, s, z$ in year $y$.

Step A1.3: Survival after fisheries to time of molting/growth/mating
Natural mortality is again applied to the population from just after the fisheries to the time just before molting/growth/mating occurs for year $y$ at $\delta t_{y}^{m}$ (generally Feb. 15). The numbers surviving to $\delta t_{y}^{m}$ in year $y$ are given by:

| $n_{y, x, m, s, z}^{3}=e^{-M_{y, x, m, s, z} \cdot\left(\delta t_{y}^{m}-\delta t_{y}^{F}\right)} \cdot n_{y, x, m, s, z}^{2}$ | A1.3 |
| :--- | :---: |

where, as above, $M$ represents the annual rate of natural mortality in year $y$ on crab classified as $x, m, s, z$.

Step A1.4: Molting, growth, and maturation
The changes in population structure due to molting, growth and maturation of immature (new shell) crab, as well as the change in shell condition for mature new shell (MAT, NS) crab to mature old shell (MAT, OS) crab due to aging, are given by:

| $n_{y, x, M A T, N S, z}^{4}=\phi_{y, x, z} \cdot \sum_{z^{\prime}} \Theta_{y, x, z, z^{\prime}} \cdot n_{y, x, I M M, N S, z^{\prime}}^{3}$ | A1.4a |
| :--- | :--- |
| $n_{y, x, I M M, N S, z}^{4}=\left(1-\phi_{y, x, z}\right) \cdot \sum_{z^{\prime}} \Theta_{y, x, z, z^{\prime}} \cdot n_{y, x, I M M, N S, z^{\prime}}^{3}$ | A1.4b |
| $n_{y, x, M A T, O S, z}^{4}=n_{y, x, M A T, O S, z}^{3}+n_{y, x, M A T, N S, z}^{3}$ | A1.4c |

where $\Theta_{y, x, z, z^{\prime}}$ is the growth transition matrix in year $y$ for an immature new shell (IMM, NS) crab of sex $x$ and pre-molt size $z$ ' to post-molt size $z$ and $\phi_{y, x, z}$ is the probability that a just-molted crab of sex $x$ and post-molt size $z$ has undergone its terminal molt to maturity (MAT). All crab that molted remain new shell (NS) crab. Additionally, all mature crab that underwent terminal molt to maturity the previous year are assumed to change shell condition from new shell to old shell (A1.4c). Note that the numbers of immature old shell (IMM, OS) crab are identically zero in the current model because immature crab are assumed to molt each year until they undergo the terminal molt to maturity; consequently, the "missing" equation for $m=I M M, s=O S$ is unnecessary.

Step A1.5: Survival to end of year, recruitment, and update to start of next year
Finally, the population abundance at the start of year $y+1$, due to natural mortality on crab from just after the time of molting/growth/mating in year $y$ until the end of the model year (June 30) and recruitment ( $R_{y, x, z}$ ) at the end of year $y$ of immature new shell (IMM, NS) crab by sex $x$ and size $z$, is given by:
$n_{y+1, x, m, s, z}=\left\{\begin{array}{ll|l|}e^{-M_{y, x, I M M, N S, z} \cdot\left(1-\delta t_{y}^{m}\right)} \cdot n_{y, x, I M M, N S, z}^{4}+R_{y, x, z} & m=I M M, s=N S \\ e^{-M_{y, x, m, s, z} \cdot\left(1-\delta t_{y}^{m}\right)} \cdot n_{y, x, m, s, z}^{4} & \text { otherwise } & \text { A1.5 } \\ \hline\end{array}\right.$

## A2. Calculation sequence when $\delta t_{\boldsymbol{y}}^{\boldsymbol{m}}<\boldsymbol{\delta} \boldsymbol{t}_{\boldsymbol{y}}^{\boldsymbol{F}}$

## Step A2.1: Survival prior to molting/growth/mating

As in the previous sequence, natural mortality is first applied to the population from the start of the model year (July 1), but this time until just prior to molting/growth/mating in year $y$ at $\delta t_{y}^{m}$ (generally Feb. 15). The numbers surviving at $\delta t_{y}^{m}$ in year $y$ are given by:

| $n_{y, x, m, s, z}^{1}=e^{-M_{y, x, m, s, z} \cdot \delta t y_{y}^{m}} \cdot n_{y, x, m, s, z}$ | A2.1 |
| :--- | :--- |

where $M$ represents the annual rate of natural mortality in year $y$ on crab classified as $x, m, s, z$.
Step A2.2: Molting, growth, and maturation
The changes in population structure due to molting, growth and maturation of immature new shell (IMM, NS) crab, as well as the change in shell condition for mature new shell (MAT, NS) crab to mature old shell (MAT, OS) crab due to aging, are given by:

| $n_{y, x, M A T, N S, z}^{2}=\phi_{y, x, z} \cdot \sum_{z^{\prime}} \Theta_{y, x, z, z^{\prime}} \cdot n_{y, x, I M M, N S, z^{\prime}}^{1}$ | A2.2a |
| :--- | :---: |
| $n_{y, x, I M M, N S, z}^{2}=\left(1-\phi_{y, x, z}\right) \cdot \sum_{z^{\prime}} \Theta_{y, x, Z, z^{\prime}} \cdot n_{y, x, I M M, N S, z^{\prime}}^{1}$ | A2.2b |
| $n_{y, x, M A T, O S, z}^{2}=n_{y, x, M A T, O S, z}^{1}+n_{y, x, M A T, N S, z}^{1}$ | A2.2c |

where $\Theta_{y, x, z, z^{\prime}}$ is the growth transition matrix in year $y$ for an immature new shell (IMM, NS) crab of sex $x$ and pre-molt size $z$ ' to post-molt size $z$ and $\phi_{y, x, z}$ is the probability that a just-molted crab of sex $x$ and post-molt size $z$ has undergone its terminal molt to maturity. Additionally, mature new shell (MAT, NS) crab that underwent their terminal molt to maturity the previous year are assumed to change shell condition from new shell to old shell (A2.2c). Again, the numbers of immature old shell crab are identically zero because immature crab are assumed to molt each year until they undergo the terminal molt to maturity.

## Step A2.3: Survival after molting/growth/mating to prosecution of fisheries

Natural mortality is again applied to the population from just after molting/growth/mating to the time at which the fisheries occur for year $y$ (at $\delta t_{y}^{F}$ ). The numbers surviving at $\delta t_{y}^{F}$ in year $y$ are then given by:

| $n_{y, x, m, s, z}^{3}=e^{-M_{y, x, m, s, z} \cdot\left(\delta t_{y}^{F}-\delta t_{y}^{m}\right)} \cdot n_{y, x, m, s, z}^{2}$ | A 2.3 |
| :--- | :---: |

where, as above, $M$ represents the annual rate of natural mortality in year $y$ on crab classified as $x, m, s, z$.
Step A2.4: Prosecution of the fisheries
The directed fishery and bycatch fisheries are modeled as pulse fisheries occurring at $\delta t_{y}^{F}$ in year $y$. The numbers that remain after the fisheries are prosecuted are given by:

| $n_{y, x, m, s, z}^{4}=e^{-F_{y, x, m, s, z}^{T} \cdot n_{y, x, m, s, z}^{3}}$ | A2.4 |
| :--- | :---: |

where $F_{y, x, m, s, z}^{T}$ represents the total fishing mortality (over all fisheries) on crab classified as $x, m, s, z$ in year $y$.

Step A2.5: Survival to end of year, recruitment, and update to start of next year
Finally, population abundance at the start of year $y+1$ due to natural mortality on crab from just after prosecution of the fisheries in year $y$ until the end of the model year (June 30) and recruitment of immature new (IMM, NS) shell crab at the end of year $y\left(R_{y, x, z}\right)$ and are given by:

$$
\begin{array}{|ll|l|}
\hline n_{y+1, x, m, s, z}= \begin{cases}e^{-M_{y, x, I M M, N S, z} \cdot\left(1-\delta t_{y}^{F}\right)} \cdot n_{y, x, I M M, N S, z}^{4}+R_{y, x, Z} & m=I M M, s=N S \\
e^{-M_{y, x, m, S, z} \cdot\left(1-\delta t_{y}^{F}\right)} \cdot n_{y, x, m, s, Z}^{4} & \text { otherwise }\end{cases} & \text { A2.5 } \\
\hline
\end{array}
$$

## B. Parameter specification

Because parameterization of many model processes (e.g., natural mortality, fishing mortality) in TCSAM02 is fairly flexible, it is worthwhile discussing how model processes and their associated parameters are configured in TCSAM02 before discussing details of the model processes themselves. Each type of model process has a set of (potentially estimable) model parameters and other information associated with it, but different "elements" of a model process can be defined that apply, for example, to different segments of the population and/or during different time blocks. In turn, several "elements" of a model parameter associated with a model process may also be defined (and applied to different elements of the process). At least one combination of model parameters and other information associated with a model process must be defined-i.e., one process element must be defined.

Model processes and parameters are configured in a "ModelParametersInfo" file, one of the three control files required for a model run (the others are the "ModelConfiguration" file and the "ModelOptions" file). As an example of the model processes and parameter specification syntax, Text Box 1 presents the part of a "ModelParametersInfo" file concerned with specifying fishing processes in the directed Tanner crab fishery.

In Text Box 1, the keyword "fisheries" identifies the model process in question. The first section, following the "PARAMETER_COMBINATIONS" keyword (up to the first set of triple blue dots), specifies the indices associated with fishing process parameters ( $\mathrm{pHM}, \mathrm{pLnC}, \mathrm{pDC} 1, \mathrm{pDC} 2, \mathrm{pDC} 3$, pDC4, pDevsLnC, pLnEffX, pLgtRet), selectivity and retention functions (idxSelFcn, idxRetFcn), and effort averaging time period (effAvgID) that apply to a single fishing process element. In this example, the indices for the selectivity and retention functions, as well as those for the effort averaging time period, constitute the "other information" specified for each fishing process element. Each fishing process element in turn applies to a specific fishery (FISHERY=1 indicates the directed fishery, in this case), time block (specified by YEAR_BLOCK), and components of the model population (specified by SEX, MATURITY STATE, and SHELL CONDITION). Using indices to identify which parameters and selectivity and retention functions apply to a given combination of fishery/time block/sex/maturity state/shell condition allows one to "share" individual parameters and selectivity and retention functions across different fishery/time block/sex/maturity state/shell condition combinations.

The second section (following the "PARAMETERS" keyword) determines the characteristics for each of the fishing process parameters, organized by parameter name (note: the parameters associated with the different selectivity and retention functions are specified in a different section of the ModelParametersInfo file). Here, each parameter name corresponds to an ADMB "param_init_bounded_number_vector" in the model code-the exception being pDevsLnC, which corresponds to an ADMB "param_init_bounded_vector_vector".

Each row under a "non-devs" parameter name in the fisheries section (e.g., pLnC) specifies the index used to associate an element of the parameter with the fishing processes defined in the PARAMETER_COMBINATIONS section, as well as characteristics of the element in the associated ADMB number_vector (upper and lower bounds, initial value, and initial estimation phase), various flags for initialization ("jitter", "resample"), definition of an associated prior probability distribution, and a label. Each row under a "devs" parameter name (e.g., pDevsLnC) specifies much the same information for the associated ADMB devs vector, with the "read" flag replacing the "initial value" entry. If "read?" is TRUE, then a vector of initial values is read from the file after all "info" rows for the devs parameter have
been read. The "jitter" flag (if set to TRUE) provides the ability to change the initial value for an element of a non-devs parameter using a randomly selected value based on the element's upper and lower bounds. For a devs parameter, an element with jitter set to TRUE is initialized using a vector of randomlygenerated numbers (subject to being a devs vector within the upper and lower bounds). The "resample" flag was intended to specify an alternative method to providing randomly-generated initial values (based on an element's prior probability distribution, rather than its upper and lower bounds), but this has not yet been fully implemented.

Some model processes apply only to specific segments of the population (e.g., growth only applies to immature, new shell crab). In general, though, a model process element can be defined to apply to any segment of the population (by specifying SEX, MATURITY STATE, and SHELL CONDITION appropriately) and range of years (by specifying YEAR_BLOCK). In turn, an element of a parameter may be "shared" across multiple processes by specifying the element's index in multiple rows of a PARAMETERS_COMBINATION block.

Text Box 1. Abbreviated example of process and parameter specifications in a "ModelParametersInfo" file for fishing mortality in TCSAM02. Only parameter combinations and parameters relevant to the directed fishery are shown. Input values are in black text, comments are in green, triple blue dots indicate additional input lines not shown.

## C. Model processes: natural mortality

The natural mortality rate applied to crab of sex $x$, maturity state $m$, shell condition $s$, and size $z$ in year $y$, $M_{y, x, m, s, z}$, can be specified using one of two parameterizations. The first parameterization option uses a ln-scale parameterization with an option to include an inverse- size dependence using Lorenzen's approach:

| $\ln M_{y, x, m, s}=\mu_{y, x, m, s}^{0}+\sum_{i=1}^{4} \delta \mu_{y, x, m, s}^{i}$ | C.1a |
| :--- | :---: |
| $M_{y, x, m, s, z}=\left\{\begin{array}{cl}\exp \left(\ln M_{y, x, m, s}\right) & \text { if Lorenzen option is not selected } \\ \exp \left(\ln M_{y, x, m, s}\right) \cdot \frac{z_{\text {base }}}{z} & \text { if Lorenzen option is selected }\end{array}\right.$ | C.1b |
| C.1c |  |

where the $\mu^{0}$ and the $\delta \mu^{i}$ 's are (potentially) estimable parameters defined for time block $T$, sex $S$ (MALE, FEMALE, or ANY), maturity M (IMMATURE, MATURE, or ANY), and shell condition $S$ (NEWSHELL, OLDSHELL, or ANY), and $\{y, x, m, s\}$ falls into the set $\{T, X, M, S\}$. In Eq. C.1c, $z_{\text {base }}$ denotes the specified reference size ( mm CW ) for the inverse-size dependence.

The second parameterization option uses an arithmetic parameterization in order to provide backward compatibility with the 2016 assessment model based on TCSAM2013. In TCSAM2013, the natural mortality rate $M_{y, x, m, s, z}$ was parameterized using:

| $M_{y, x, m=I M M, s, Z}=M^{\text {base }} \cdot \delta M_{I M M}$ | C.2a |
| :--- | :---: |
| $M_{y, x, m=M A T, s, Z}=\left\{\begin{array}{cc}M^{\text {base }} \cdot \delta M_{x, M A T} & \text { otherwise } \\ M^{\text {base }} \cdot \delta M_{x, M A T} \cdot \delta M_{x, M A T}^{T} & 1980 \leq y \leq 1984\end{array}\right.$ | C.2b |

where $M^{\text {base }}$ was a fixed value ( $0.23 \mathrm{yr}^{-1}$ ), $\delta M_{I M M}$ was a multiplicative factor applied for all immature crab, the $\delta M_{\chi, M A T}$ were sex-specific multiplicative factors for mature crab, and the $\delta M_{x, M A T}^{T}$ were additional sex-specific multiplicative factors for mature crab during the 1980-1984 time block (which has been identified as a period of enhanced natural mortality on mature crab, the mechanisms for which are not understood). While it would be possible to replicate Eq.s C.2a and C.2b using ln-scale parameters, TCSAM2013 also placed informative arithmetic-scale priors on some of these parameters-and this could not be duplicated on the ln-scale. Consequently, the second option uses the following parameterization, where the parameters (and associated priors) are defined on the arithmetic-scale:

| $\ln M_{y, x, m, s}=\ln \left[\mu_{y, x, m, s}^{0}\right]+\sum_{i=1}^{4} \ln \left[\delta \mu_{y, x, m, s}^{i}\right]$ | C.3a |
| :--- | :---: |

A system of equations identical to C.2a-b can be achieved under the following assignments:

| $\mu_{\{y, x, m, S\} \in\{T=A L L, X=A L L, M=A L L, S=A L L\}}^{0}=M^{\text {base }}$ | C. 4 a |
| :--- | :---: |
| $\delta \mu_{\{y, x, m, S\} \in\{T=A L L, X=A L L, M=I M M, S=A L L\}}^{1}=\delta M_{I M M}$ | C. 4 e |
| $\delta \mu_{\{y, x, m, s\} \in\{T=A L L, X=x, M=M A T, S=A L L\}}^{1}=\delta M_{x, M A T}$ | C. 4 f |
| $\delta \mu_{\{y, x, m, S\} \in\{T=1980-1984, X=x, M=M A T, S=A L L\}}^{2}=\delta M_{x, M A T}^{T}$ | C. 4 g |

where unassigned $\delta \mu_{y, x, m, s}^{i}$ are set equal to 1 . Pending further model testing using alternative model configurations, the TCSAM2013 option is standard.

It is worth noting explicitly that, given the number of potential parameters above that could be used, extreme care must be taken when defining a model to achieve a set of parameters that are not confounded and are, at least potentially, estimable.

## D. Model processes: growth

Because Tanner crab are assumed to undergo a terminal molt to maturity, in TCSAM02 only immature crab experience growth. Annual growth of immature crab is implemented as using two options, the first based on a formulation used in Gmacs and the second (mainly for purposes of backward compatibility) based on that used in TCSAM2013. In TCSAM02, growth can vary by time block and sex, so it is expressed by sex-specific transition matrices for time block $t, \Theta_{t, x, z, z^{\prime}}$, that specify the probability that crab of sex $x$ in pre-molt size bin $z^{\prime}$ grow to post-molt size bin $z$ at molting.

In the Gmacs-like approach (the standard approach as of May, 2017), the sex-specific growth matrices are given by:

| $\Theta_{t, x, z, z^{\prime}}=c_{t, x, z^{\prime}} \cdot \int_{z-b i n / 2}^{z+\text { bin } / 2} \Gamma\left(\frac{z^{\prime \prime}-\bar{z}_{t, x, z^{\prime}}}{\beta_{t, x}}\right) d z^{\prime \prime}$ | Sex-specific $(x)$ transition matrix for <br> growth from pre-molt $z^{\prime}$ to post-molt $z$, <br> with $z \geq z^{\prime}$ | D.1a |
| :--- | :--- | :--- |
| $c_{t, x, z^{\prime}}=\left[\int_{z^{\prime}}^{\infty} \Gamma\left(\frac{z^{\prime \prime}-\bar{z}_{t, x, z^{\prime}}}{\beta_{t, x}}\right) d z^{\prime \prime}\right]^{-1}$ | Normalization constant so <br> $1=\sum_{z} \Theta_{t, x, z, z^{\prime}}$ | D.1b |
| $\bar{z}_{t, x, z^{\prime}}=e^{a_{t, x} \cdot z^{\prime} b_{t, x}}$ | Mean size after molt, given pre-molt size <br> $z^{\prime}$ | D.1c |

where the integral represents a cumulative gamma distribution across the post-molt ( $z$ ) size bin. This approach may have better numerical stability properties than the TCSAM2013 approach below.

The TCSAM2013 approach is an approximation to the Gmacs approach, where the sex-specific growth matrices $\Theta_{t, x, z, z^{\prime}}$ are given by

| $\Theta_{t, x, z, z^{\prime}}=c_{t, x, z^{\prime}} \cdot \Delta_{z, z^{\prime}} \alpha_{t, x, z^{\prime}}-1$ |  |  |
| :--- | :--- | :---: |
| $e^{-\frac{\Delta_{z, z^{\prime}}}{\beta_{t, x}}}$ | Sex-specific $(x)$ transition matrix for <br> growth from pre-molt $z^{\prime}$ to post-molt $z$, <br> with $z \geq z^{\prime}$ | D.2a |
| $c_{t, x, z^{\prime}}=\left[\sum_{z^{\prime}} \Delta_{z, z^{\prime}} \alpha_{t, x, z^{\prime}}-1\right.$ |  |  |
| $\left.e^{-\frac{\Delta_{z, z^{\prime}}}{\beta_{t, x}}}\right]^{-1}$ | Normalization constant so <br> $1=\sum_{z} \Theta_{t, x, z, z^{\prime}}$ | D.2b |
| $\Delta_{z, z^{\prime}}=z-z^{\prime}$ | Actual growth increment | D.2c |
| $\alpha_{t, x, z^{\prime}}=\left[\bar{z}_{t, x, z^{\prime}}-z^{\prime}\right] / \beta_{t, x}$ | Mean molt increment, scaled by $\beta_{t, x}$ | D.2d |
| $\bar{z}_{t, x, z^{\prime}}=e^{a_{t, x} \cdot z^{\prime} b_{t, x}}$ | Mean size after molt, given pre-molt size <br> $z^{\prime}$ | D.2e |

In both approaches, the $a_{t, x,} b_{t, x,}$, and $\beta_{t, x}$ are arithmetic-scale parameters with imposed bounds. $\Theta_{t, x, z, z^{\prime}}$ is used to update the numbers-at-size for immature crab, $n_{y, x, z}$, from pre-molt size $z^{\prime}$ to post-molt size $z$ using:

| $n_{y, x, z}^{+}=\sum_{z^{\prime}} \Theta_{t, x, z, z^{\prime}} \cdot n_{y, x, z^{\prime}}$ | numbers at size of immature crab after <br> growth | D. 3 |
| :--- | :--- | :---: |

where $y$ falls within time block $t$ (see also Eq.s A1.4a-b and A2.2a-b).
Priors using normal distributions are imposed on $a_{t, x}$ and $b_{t, x}$ in TCSAM2013, with the values of the hyper-parameters hard-wired in the model code. While priors may be defined for the associated parameters here, these are identified by the user in the model input files and are not hard-wired in the model code.

## E. Model processes: maturity (terminal molt)

Maturation of immature crab in TCSAM02 is based on a similar approach to that taken in TCSAM2013, except that the sex- and size-specific probabilities of terminal molt for immature crab, $\phi_{t, x, z}$ (where size $z$ is post-molt size), can vary by time block. After molting and growth, the numbers of (new shell) crab at post-molt size $z$ remaining immature, $n_{y, x, I M M, N S, z}^{+}$, and those maturing, $n_{x, M A T, N S, z}^{+}$, are given by:

| $n_{y, x, I M M, N S, z}^{+}=$ | $\left(1-\phi_{t, x, z}\right) \cdot n_{y, x, I M M, N S, z}$ | crab remaining immature | E.1a |
| :--- | :---: | :--- | :--- |
| $n_{y, x, M A T, N S, z}^{+}=$ | $\phi_{t, x, z} \cdot n_{y, x, I M M, N S, z}$ | crab maturing (terminal molt) | E.1b |

where $y$ falls in time block $t$ and $n_{y, x, I M M, N S, Z}$ is the number of immature, new shell crab of sex $x$ at postmolt size $z$.

The sex- and size-specific probabilities of terminal molt, $\phi_{t, x, z}$, are related to logit-scale model parameters $p_{t, x, z}^{\text {mat }}$ by:

| $\phi_{t, F E M, Z}=\left\{\begin{array}{lll}\frac{1}{1+e^{p_{t, F E M, z}^{m a t}}} & z \leq z_{t, F E M}^{m a t} \\ 1 & z>z_{t, F E M}^{m a t}\end{array}\right.$ | female probabilities of maturing at <br> post-molt size $z$ | E.2a |
| :--- | :--- | :--- | :--- |
| $\phi_{t, M A L E, z}=\left\{\begin{array}{lll}\frac{1}{1+e^{p_{t, M A L E, z}^{m a t}}} & z \leq z_{t, M A L E}^{\text {mat }} \\ 1 & z>z_{t, M A L E}^{\text {mat }}\end{array}\right.$ | male probabilities of maturing at <br> post-molt size $z$ | E.2b |

where the $z_{t, x}^{\text {mat }}$ are constants specifying the minimum pre-molt size at which to assume all immature crab will mature upon molting. The $z_{t, x}^{m a t}$ are used here pedagogically; in actuality, the user specifies the number of logit-scale parameters to estimate (one per size bin starting with the first bin) for each sex, and this determines the $z_{t, x}^{m a t}$ used above. This parameterization is similar to that implemented in TCSAM2013 for the 2016 assessment model.

Second difference penalties are applied to the parameter estimates in TCSAM2013's objective function to promote relatively smooth changes in these parameters with size. Similar penalties (smoothness, nondecreasing) can be applied in TCSAM02.

## F. Model processes: recruitment

Recruitment in TCSAM02 consists of immature new shell crab entering the population at the end of the model year (June 30). Recruitment in TCSAM02 has a similar functional form to that used in TCSAM2013, except that the sex ratio at recruitment is not fixed at $1: 1$ and multiple time blocks can be specified. In TCSAM2013, two time blocks were defined: "historical" (model start to 1974) and "current" (1975-present), with "current" recruitment starting in the first year of NMFS survey data. In TCSAM02, recruitment in year $y$ of immature new shell crab of sex $x$ at size $z$ is specified as

| $R_{y, x, z}=\dot{R}_{y} \cdot \ddot{R}_{y, x} \cdot \dddot{R}_{y, z}$ | recruitment of immature, new shell crab <br> by sex and size bin | F. 1 |
| :--- | :--- | :--- |

where $\dot{R}_{y}$ represents total recruitment in year $y$ and $\ddot{R}_{y, x}$ represents the fraction of sex $x$ crab recruiting, and $\dddot{R}_{y, z}$ is the size distribution of recruits, which is assumed identical for males and females.

Total recruitment in year $y, \dot{R}_{y}$, is parameterized as

| $\dot{R}_{y}=e^{p L n R_{t}+\delta R_{t, y}} \quad y \in t$ | total recruitment in year $y$ | F. 2 |
| :--- | :--- | :--- |

where $y$ falls within time block $t, p \operatorname{Ln} R_{t}$ is the ln-scale mean recruitment parameter for $t$, and $\delta R_{t, y}$ is an element of a "devs" parameter vector for $t$ (constrained such that the elements of the vector sum to zero over the time block).

The fraction of crab recruiting as sex $x$ in year $y$ in time block $t$ is parameterized using the logistic model

| $\ddot{R}_{y, x}=\left\{\begin{array}{cc}\frac{1}{1+e^{p L g t R x_{t}}} & x=M A L E \\ 1-\ddot{R}_{y, M A L E} & x=F E M A L E\end{array} \quad y \in t\right.$ | sex-specific fraction recruiting in year $y$ | F. 3 |
| :--- | :---: | :---: | :---: |

where $p L g t R x_{t}$ is a logit-scale parameter determining the sex ratio in time block $t$.
The size distribution for recruits in time block $t, \dddot{R}_{t, z}$, is assumed to be a gamma distribution and is parameterized as

| $\dddot{R}_{t, z}=c^{-1} \cdot \Delta_{z}{ }^{\frac{\alpha_{t}}{\beta_{t}}-1} \cdot e^{-\frac{\Delta_{z}}{\beta_{t}}}$ | size distribution of recruiting crab | F .4 |
| :--- | :--- | :--- |
| $c_{t}=\sum_{z} \Delta_{z}^{\frac{\alpha_{t}}{\beta_{t}}-1} \cdot e^{-\frac{\Delta_{z}}{\beta_{t}}}$ | normalization constant so that $1=\sum_{z} \dddot{R}_{t, z}$ | F .5 |
| $\Delta_{z}=z+\delta z / 2-z_{\text {min }}$ | offset from minimum size bin | F .6 |
| $\alpha_{t}=e^{\text {pLnRa } a_{t}}$ | gamma distribution location parameter | F .7 |
| $\beta_{t}=e^{\text {pLnRb }} t$ | gamma distribution shape parameter | F .8 |

where $p \operatorname{LnR} a_{t}$ and $p L n R b_{t}$ are the ln-scale location and shape parameters and the constant $\delta z$ is the size bin spacing.

A final time-blocked parameter, $p L n R C V_{t}$, is associated with the recruitment process representing the $\ln$ scale coefficient of variation (cv) in recruitment variability in time block $t$. These parameters are used to apply priors on the recruitment "devs" in the model likelihood function.

## G. Selectivity and retention functions

Selectivity and retention functions in TCSAM02 are specified independently from the fisheries and surveys to which they are subsequently applied. This allows a single selectivity function to be "shared" among multiple fisheries and/or surveys, as well as among multiple time block/sex/maturity state/shell condition categories, if so desired.

Currently, the following functions are available for use as selectivity or retention curves in a model:

| $S_{Z}=\left\{1+e^{-\beta \cdot\left(z-z_{50}\right)}\right\}^{-1}$ | standard logistic | G. 1 |
| :---: | :---: | :---: |
| $S_{z}=\left\{1+e^{-\beta \cdot\left(z-\exp \left(\ln z_{50}\right)\right)}\right\}^{-1}$ | logistic w/ alternative parameterization | G. 2 |
| $S_{Z}=\left\{1+e^{-\ln (19) \cdot \frac{\left(z-z_{50}\right)}{\Delta z_{955}-50}}\right\}^{-1}$ | logistic w/ alternative parameterization | G. 3 |
| $S_{z}=\left\{1+e^{-\ln (19) \cdot \frac{\left(z-z_{50}\right)}{\exp \left(\ln \Delta z_{95}-50\right)}}\right\}^{-1}$ | logistic w/ alternative parameterization | G. 4 |
| $S_{Z}=\left\{1+e^{-\ln (19) \cdot \frac{\left(z-\exp \left(\ln Z_{50}\right)\right)}{\exp \left(\ln \Delta Z_{95-50}\right)}}\right\}^{-1}$ | logistic w/ alternative parameterization | G. 5 |
| $S_{z}=\frac{1}{1+e^{-\beta_{a} \cdot\left(z-z_{a 50}\right)}} \cdot \frac{1}{1+e^{\beta_{a} \cdot\left(z-z_{d 50}\right)}}$ | double logistic | G. 6 |
|  | double logistic with alt. parameterization | G. 7 |
| $\begin{aligned} & \quad S_{z}=\frac{1}{1+e^{-\ln (19) \cdot \frac{\left(z-z_{a 50}\right)}{\exp \left(\ln \Delta z_{a(95-50))}\right.}} \cdot \frac{1}{1+e^{\ln (19) \cdot \frac{\left(z-z_{d 50}\right)}{\exp \left(\ln \Delta z_{d(95-50))}\right.}}}} \begin{array}{l} \text { where } z_{d 50}=\left[z_{a 50}+\exp \left(\ln \Delta z_{a(95-50)}\right)+\exp \left(\ln \Delta z_{d(95-50)}\right)\right] \end{array} \end{aligned}$ | double logistic with alt. parameterization | G. 8 |
| $\begin{gathered} S_{z}=\frac{1}{1+e^{-\ln (19) \cdot \frac{\left(z-\exp \left(\ln z_{a 50}\right)\right)}{\exp \left(\ln \Delta z_{a(95-50)}\right)}} \cdot \frac{1}{1+e^{\ln (19) \cdot} \cdot \frac{\left(z-z_{d 50}\right)}{\exp \left(\ln \Delta z_{d(9550)}\right)}}} \\ \text { where } z_{d 50}=\left[\exp \left(\ln z_{a 50}\right)+\exp \left(\ln \Delta z_{a(95-50)}\right)+\exp \left(\ln \Delta z_{d(95-50)}\right)\right] \end{gathered}$ | double logistic with alt. parameterization | G. 9 |
| $S_{z}=\frac{1}{1+e^{-\beta_{a} \cdot\left(z-z_{a 50}\right)}} \cdot \frac{1}{1+e^{\beta_{d} \cdot\left(z-\left[z_{a 50}+\exp \left(\ln Z_{d 50-a 50}\right)\right]\right)}}$ | double logistic with alt. parameterization | G. 10 |

A double normal selectivity function (requiring 6 parameters to specify) has also been implemented as an alternative to the double logistic functions. In the above functions, all symbols (e.g., $\beta, z_{50}, \Delta z_{95-50}$ ) represent parameter values, except " $z$ " which represents crab size.

Selectivity parameters are defined independently of the functions themselves, and subsequently assigned. It is thus possible to "share" parameters across multiple functions. The "parameters" used in selectivity functions are further divided into mean parameters across a time block and annual deviations within a time block. To accommodate the 6-parameter double normal equation, six "mean" parameter sets (pS1, $p S 2, \ldots, p S 6$ ) and six associated sets of "devs" parameter vectors ( $p$ DevsS1, $p$ DevsS2, $\ldots, p \operatorname{DevsS6}$ ) are defined to specify the parameterization of individual selectivity/retention functions. Thus, for example, $z_{50}$ in eq. F 1 is actually expressed as $z_{50, y}=\bar{z}_{50}+\delta z_{50, y}$ in terms of model parameters $p S 1$ and $p \operatorname{DevSS} 1_{y}$, where $\bar{z}_{50}=p S 1$ is the mean size-at- $50 \%$-selected over the time period and $\delta z_{50, y}=$ $p \operatorname{DevsS} 1_{y}$ is the annual deviation.

Finally, three different options to normalize individual selectivity curves are provided: 1) no normalization, 2 ) specifying a fully-selected size, and 3 ) re-scaling such that the maximum value of the
re-scaled function is 1 . A normalization option must be specified in the model input files for each defined selectivity/retention curve.

## H. Fisheries

Unlike TCSAM2013, which explicitly models 4 fisheries that catch Tanner crab (one as a directed fishery, three as bycatch), there is no constraint in TCSAM02 on the number of fisheries that can be incorporated in the model. All fisheries are modeled as "pulse" fisheries occurring at the same time.

TCSAM02 uses the Gmacs approach to modeling fishing mortality (also implemented in TCSAM2013). The total (retained + discards) fishing mortality rate, $F_{f, y, x, m, s, z}$, in fishery $f$ during year $y$ on crab in state $x, m, s$, and $z$ (i.e., sex, maturity state, shell condition, and size) is related to the associated fishery capture rate $\phi_{f, y, x, m, s, z}$ by

| $F_{f, y, x, m, s, z}=\left[h_{f, t} \cdot\left(1-\rho_{f, y, x, m, s, z}\right)+\rho_{f, y, x, m, s, z}\right] \cdot \phi_{f, y, x, m, s, z}$ | fishing mortality rate | H.1 |
| :--- | :--- | :--- |

where $h_{f, t}$ is the handling (discard) mortality for fishery $f$ in time block t (which includes year $y$ ) and $\rho_{f, y, x, m, s, z}$ is the fraction of crabs in state $x, m, s, z$ that were caught and retained (i.e., the retention function). The retention function is assumed to be identically 0 for females in a directed fishery and for both sexes in a bycatch fishery.

In TCSAM2013, the same retention function (in each of two time blocks) was applied to male crab regardless of maturity state or shell condition. Additionally, full retention of large males was assumed, such that the retention function essentially reached 1 at large sizes. In TCSAM02, different retention functions can be applied based on maturity state and/or shell condition, and "max retention" is now an (potentially) estimable logit-scale parameter. Thus, in TCSAM02, the retention function $\rho_{f, y, x, m, s, z}$ is given by

| $\rho_{f, y, x, m, s, z}=\frac{1}{1+e^{\rho_{f, t, x, m, s}}} \cdot R_{f, y, x, m, s, z}$ | retention function | H. 2 |
| :--- | :--- | :--- |

where $f$ corresponds to the directed fishery, $y$ is in time block $t, x=$ MALE, $\rho_{f, t, x, m, s}$ is the corresponding logit-scale "max retention" parameter, and $R_{f, y, x, m, s, z}$ is the associated selectivity/retention curve.

If $n_{y, x, m, s, z}$ is the number of crab classified as $x, m, s, z$ in year $y$ just prior to the prosecution of the fisheries, then

| $c_{f, y, x, m, s, z}=\frac{\phi_{f, y, x, m, s, z}}{F_{y, x, m, s, z}^{T}} \cdot\left[1-e^{\left.-F_{y, x, m, s, z}^{T}\right] \cdot n_{y, x, m, s, z}}\right.$ | number of crab <br> captured | H.3 |
| :--- | :--- | :--- |

is the number of crab classified in that state that were captured by fishery $f$, where $F_{y, x, m, s, z}^{T}=$ $\sum_{f} F_{f, y, x, m, s, z}$ represents the total (across all fisheries) fishing mortality on those crab. The number of crab retained in fishery $f$ classified as $x, m, s, z$ in year $y$ is given by

$$
\begin{array}{|l|l|l|}
\hline r_{f, y, x, m, s, z}=\frac{\rho_{f, y, x, m, s, z} \cdot \phi_{f, y, x, m, s, z}}{F_{y, x, m, s, z}^{T}} \cdot\left[1-e^{\left.-F_{y, x, m, s, z}^{T}\right] \cdot n_{y, x, m, s, z}}\right. & \begin{array}{l}
\text { number of } \\
\text { retained crab }
\end{array} & \text { H. } 4 \\
\hline
\end{array}
$$

while the number of discarded crab, $d_{f, y, x, m, s, z}$, is given by

$$
\begin{array}{|l|l|l|}
\hline d_{f, y, x, m, s, z}=\frac{\left(1-\rho_{f, y, x, m, s, z}\right) \cdot \phi_{f, y, x, m, s, z}}{F_{y, x, m, s, z}^{T}} \cdot\left[1-e^{\left.-F_{y, x, m, s, z}^{T}\right] \cdot n_{y, x, m, s, z}}\right. & \begin{array}{l}
\text { number of } \\
\text { discarded crab }
\end{array} & \text { H. } 5 \\
\hline
\end{array}
$$

and the discard mortality, $d m_{f, y, x, m, s, z}$, is

$$
\begin{array}{|l|l|l|}
\hline d m_{f, y, x, m, s, z}=\frac{h_{f, y} \cdot\left(1-\rho_{f, y, x, m, s, z}\right) \cdot \phi_{f, y, x, m, s, z}}{F_{y, x, m, s, z}^{T}} \cdot\left[1-e^{\left.-F_{y, x, m, z}^{T}\right]}\right] \cdot n_{y, x, m, s, z} & \begin{array}{l}
\text { discard } \\
\text { mortality } \\
\text { (numbers) }
\end{array} & \text { H. } 6 \\
\hline
\end{array}
$$

The capture rate $\phi_{f, y, x, m, s, z}$ (not the fishing mortality rate $F_{f, y, x, m, s, z}$ ) is modeled as a function separable into separate year and size components such that

| $\phi_{f, y, x, m, s, z}=\phi_{f, y, x, m, s} \cdot S_{f, y, x, m, s, z}$ | fishing capture <br> rate | H. 7 |
| :--- | :--- | :--- |

where $\phi_{f, y, x, m, s}$ is the fully-selected capture rate in year $y$ and $S_{f, y, x, m, s, z}$ is the size-specific selectivity.
The fully-selected capture rate $\phi_{f, y, x, m, s}$ for $y$ in time block $t$ is parameterized in the following manner:

$$
\begin{array}{|l|c}
\hline \phi_{f, y, x, m, s}=\exp \left(\overline{\operatorname{lnc}}_{f, t, x, m, s}+p \operatorname{Devs} C_{f, y, x, m, s}\right) & \text { H. } 8
\end{array}
$$

where the $p \operatorname{Devs} C_{f, y, x, m, s}$ are elements for year $y$ in time block $t$ of a "devs" vectors representing annual variations from the ln-scale mean fully-selected capture rate $\overline{\ln }_{f, t, x, m, s}$. The latter is expressed in terms of model parameters as

| $\overline{\ln C_{f, t, x, m, s}}=p \operatorname{LnC} C_{f, t, x, m, s}+\sum_{i=1}^{4} \delta C_{f, t, x, m, s}^{i}$ | H. 9 |
| :--- | :---: |

where the $p L n C_{f, t, x, m, s}$ is the mean In-scale capture rate (e.g., for mature males) and the $\delta C_{f, t, x, m, s}^{i}$ are lnscale offsets.

## I. Surveys

If $n_{y, x, m, s, z}$ is the number of crab classified as $x, m, s, z$ in year $y$ just prior to the prosecution of a survey, then the survey abundance, $a_{v, y, x, m, s, z}$, of crab classified in that state by survey $v$ is given by

| $a_{v, y, x, m, s, z}=q_{v, y, x, m, s, z} \cdot n_{y, x, m, s, z}$ | survey abundance | I. |
| :--- | :--- | :---: |

where $q_{v, y, x, m, s, z}$ is the size-specific survey catchability on this component of the population.
The survey catchability $q_{v, y, x, m, s, z}$ is decomposed in the usual fashion into separate time block and size components such that, for $y$ in time block $t$ :

| $q_{v, y, x, m, s, z}=q_{v, t, x, m, s} \cdot S_{v, t, x, m, s, z}$ | survey catchability | I.2 |
| :--- | :--- | :---: |

where $q_{v, t, x, m, s}$ is the fully-selected catchability in time block $t$ and $S_{v, t, x, m, s, z}$ is the size-specific survey selectivity.

The fully-selected catchability $q_{v, t, x, m, s}$ is parameterized in a fashion similar to that for fully-selected fishery capture rates (except that annual "devs" are not included) in the following manner:

| $q_{v, t, x, m, s}=\exp \left(p L n Q_{v, t, x, m, s}+\sum_{i=1}^{4} \delta Q_{v, t, x, m, s}^{i}\right)$ | I. 3 |
| :--- | :--- |

where the $p \operatorname{Ln} Q_{v, t, x, m, s}$ is the mean ln-scale catchability (e.g., for mature males) and the $\delta Q_{v, t, x, m, s}^{i}$ are $\ln -$ scale offsets.

## J. Model fitting: objective function equations

The TCSAM02 model is fit by minimizing an objective function, $\sigma$, with additive components consisting of: 1) negative log-likelihood functions based on specified prior probability distributions associated with user-specified model parameters, and 2) several negative log-likelihood functions based on input data components, of the form:

| $\sigma=-2 \sum_{p} \lambda_{p} \cdot \ln \left(\wp_{p}\right)-2 \sum_{l} \lambda_{l} \cdot \ln \left(\mathcal{L}_{l}\right)$ | model objective function | J. 1 |
| :--- | :--- | :--- |

where $\wp_{p}$ represents the $p$ th prior probability function, $\mathcal{L}_{l}$ represents the lth likelihood function, and the $\lambda$ 's represent user-adjustable weights for each component.

## Prior Probability Functions

Prior probability functions can be associated with each model parameter or parameter vector by the user in the model input files (see Section L below for examples on specifying priors).

## Likelihood Functions

The likelihood components included in the model's objective function are based on normalized size frequencies and time series of abundance or biomass from fishery or survey data. Survey data optionally consists of abundance and/or biomass time series for males, females, and/or all crab (with associated survey cv's), as well as size frequencies by sex, maturity state, and shell condition. Fishery data consists of similar data types for optional retained, discard, and total catch components.

Size frequency components
Likelihood components involving size frequencies are based on multinomial sampling:

| $\ln (\mathcal{L})=\sum_{y} n_{y, c} \cdot \sum_{z}\left\{p_{y, c, z}^{o b s} \cdot \ln \left(p_{y, c, z}^{m o d}+\delta\right)-p_{y, c, z}^{o b s} \cdot \ln \left(p_{y, c, z}^{o b s}+\delta\right)\right\}$ | multinomial <br> log-likelihood | J .2 |
| :--- | :--- | :--- |

where the $y$ 's are years for which data exists, " $c$ " indicates the population component classifiers (i.e., sex, maturity state, shell condition) the size frequency refers to, $n_{y, c}$ is the classifier-specific effective sample size for year y, $p_{y, c, z}^{o b s}$ is the observed size composition in size bin $z$ (i.e., the size frequency normalized to sum to 1 across size bins for each year), $p_{y, c, z}^{m o d}$ is the corresponding model-estimated size composition, and $\delta$ is a small constant. The manner in which the observed and estimated size frequencies for each data component are aggregated (e.g., over shell condition) prior to normalization is specified by the user in the model input files. Data can be entered in input files at less-aggregated levels of than will be used in the model; it will be aggregated in the model to the requested level before fitting occurs.

## Aggregated abundance/biomass components

Likelihood components involving aggregated (over size, at least) abundance and or biomass time series can be computed using one of three potential likelihood functions: the normal, the lognormal, and the "norm2". The likelihood function used for each data component is user-specified in the model input files.

The $\ln$-scale normal likelihood function is

| $\ln \left(\mathcal{L}^{N}\right)_{c}=-\frac{1}{2} \sum_{y}\left\{\frac{\left[a_{y, c}^{o b s}-a_{y, c}^{m o d}\right]^{2}}{\sigma_{y, c}^{2}}\right\}$ | normal log- <br> likelihood | J. 3 |
| :--- | :--- | :---: |

where $a_{y, c}^{o b s}$ is the observed abundance/biomass value in year $y$ for aggregation level $c, a_{y, c}^{m o d}$ is the associated model estimate, and $\sigma_{y, c}^{2}$ is the variance associated with the observation.

The ln-scale lognormal likelihood function is

| $\ln \left(\mathcal{L}^{L N}\right)_{c}=-\frac{1}{2} \sum_{y}\left\{\frac{\left[\ln \left(a_{y, c}^{o b s}+\delta\right)-\ln \left(a_{y, c}^{\bmod }+\delta\right)\right]^{2}}{\sigma_{y, c}^{2}}\right\}$ | $\begin{array}{l}\text { lognormal log- } \\ \text { likelihood }\end{array}$ | J. 4 |
| :--- | :--- | :--- |

where $a_{y, c}^{o b s}$ is the observed abundance/biomass value in year $y$ for aggregation level $c, a_{y, c}^{m o d}$ is the associated model estimate, and $\sigma_{y, c}^{2}$ is the $\ln$-scale variance associated with the observation.

For consistency with TCSAM2013, a third type, the "norm2", may also be specified

| $\ln \left(\mathcal{L}^{N 2}\right)_{x}=-\frac{1}{2} \sum_{y}\left[a_{y, x}^{o b s}-a_{y, x}^{m o d}\right]^{2}$ | "norm2" log-likelihood | J. 5 |
| :--- | :--- | :--- |

This is equivalent to specifying a normal log-likelihood with $\sigma_{y, x}^{2} \equiv 1.0$. This is the standard likelihood function applied tin TCSAM2013 to fishery catch time series.

Growth data
Growth (molt increment) data can be fit as part of a TCSAM02 model. Multiple datasets can be fit at the same time. The likelihood for each dataset $\left(\mathrm{L}_{d}\right)$ is based on the same gamma distribution used in the growth model:
$\mathrm{L}_{d}=-\sum_{i \in d} \ln \left\{\Gamma\left(\frac{\tilde{z}_{i}-\bar{z}_{y_{i}, x_{i}, z_{i}}}{\beta_{y_{i}, x_{i}}}\right)\right\}$
gamma log-likelihood
J. 6
where $z_{i}$ and $\tilde{z}_{i}$ are the pre-molt and post-molt sizes for individual $i$ (of sex $x_{i}$ collected in year $y_{i}$ ) in dataset $d$, respectively, $\bar{z}_{y_{i}, x_{i}, z_{i}}$ is the predicted mean post-molt size for individual $i$, and $\beta_{y_{i}, x_{i}}$ is the scale factor for the gamma distribution corresponding to individual $i$.

## Maturity ogive data

Annual maturity ogive data, the observed proportions-at-size of mature crab in a given year, can also be fit as part of a TCSAM02 model. This data consists of proportions of mature crab observed within a size bin, as well as the total number of observations for that size bin. The proportions are assumed to represent the fraction of new shell mature crab (i.e., having gone through terminal molt within the previous growth season) to all new shell crab within the size bin in that year. Multiple datasets can be fit at the same time. The likelihood for each observation is based on a binomial distribution with sample size equal to the
number of observations within the corresponding size bin, so the likelihood for each dataset $\left(\mathrm{L}_{m}\right)$ is given by:

$$
\begin{array}{|l|l|l|}
\hline \mathrm{L}_{m}=\sum_{y, z} n_{y, z} \cdot\left\{p_{y, z}^{o b s} \cdot \ln \left(p_{y, z}^{m o d}+\delta\right)+\left(1-p_{y, z}^{o b s}\right) \cdot \ln \left(1-p_{y, z}^{m o d}+\delta\right)\right\} & \begin{array}{l}
\text { binomial log- } \\
\text { likelihood }
\end{array} & \text { J. } 7 \\
\hline
\end{array}
$$

where $y$ is a year, $z$ is a size bin, $n_{y, z}$ is the total number of classified crab in size bin $z$ in year $y, p_{y, z}^{o b s}$ is the observed ratio of mature, new shell males to total new shell males in size bin z in year $\mathrm{y}, p_{y, z}^{o b s}$ is the corresponding model-predicted ratio, and $\delta$ is a small constant to prevent trying to calculate $\ln (0)$.

## Effort data

In both TCSAM2013 and TCSAM02, fishery-specific effort data is used to predict annual fully-selected fishery capture rates for Tanner crab bycatch in the snow crab and Bristol Bay red king crab fisheries in the period before at-sea observer data is available (i.e., prior to 1991), based on the assumed relationship

$$
F_{f, y}=q_{f} \cdot E_{f, y}
$$

where $F_{f, y}$ is the fully-selected capture rate in fishery f in year $\mathrm{y}, q_{f}$ is the estimated catchability in fishery f, and $E_{f, y}$ is the reported annual, fishery-specific effort (in pots). In TCAM2013, the fishery $q$ 's are estimated directly from the ratio of fishery mean $F$ to mean $E$ over the time period $\left(t_{f}\right)$ when at-sea observer data is available from which to estimate the $F_{f, y}$ 's as parameters:

$$
q_{f}=\frac{\sum_{y \in t_{f}} F_{f, y}}{\sum_{y \in t_{f}} E_{f, y}} .
$$

Note that, in this formulation, the fishery $q$ 's are not parameters (i.e., estimated via maximizing the likelihood) in the model. In TCSAM2013, the time period over which $q$ is estimated for each fishery is hard-wired. This approach is also available as an option in TCSAM02, although different time periods for the averaging can be specified in the model options file.

A second approach to effort extrapolation in which the fishery $q$ 's are fully-fledged parameters estimated as part of maximizing the likelihood is provided in TCSAM02 as an option, as well. In this case, the effort data is assumed to have a lognormal error distribution and the following negative log-likelihood components are included in the overall model objective function:

$$
L_{f}=\sum_{y} \frac{\left(\ln \left(E_{f, y}+\delta\right)-\ln \left(\frac{F_{f, y}}{q_{f}}+\delta\right)\right)^{2}}{2 \cdot \sigma_{f}^{2}}
$$

where $\sigma_{f}^{2}$ is the assumed $\ln$-scale variance associated with the effort data and $\delta$ is a small value so that the arguments of the ln functions do not go to zero.

## Aggregation fitting levels

A number of different ways to aggregate input data and model estimates prior to fitting likelihood functions have been implemented in TCSAM02. These include:

| Abundance/Biomass <br> by | Size Conpositions <br> by |  |
| :---: | :---: | :---: |
| total <br> extended by |  |  |
| x, mature only | total | x |
| $\mathrm{x}, \mathrm{m}$ | x | $\mathrm{x}, \mathrm{m}$ |
| $\mathrm{x}, \mathrm{s}$ | -- |  |
| $\mathrm{x}, \mathrm{m}, \mathrm{s}$ | $\mathrm{x}, \mathrm{m}$ | m |
|  |  | s |
|  | $\mathrm{x}, \mathrm{s}$ | -- |
|  | $\mathrm{x}, \mathrm{m}, \mathrm{s}$ | s |
|  |  |  |
|  |  |  |

where $x, m$, s refer to sex, maturity state and shell condition and missing levels are aggregated over. For size compositions that are "extended by" $x, m, s$, or $\{x, m\}$, this involves appending the size compositions corresponding to each combination of "extended by" factor levels, renormalizing the extended composition to sum to 1 , and then fitting the extended composition using a multinomial likelihood.

## K. Devs vectors

For TCSAM02 to accommodate arbitrary numbers of fisheries and time blocks, it is necessary to be able to define arbitrary numbers of "devs" vectors. This is currently not possible using the ADMB C++ libraries, so TCSAM02 uses an alternative implementation of devs vectors from that implemented in ADMB. For the 2017 assessment, an $n$-element "devs" vector was implemented using an $n$-element bounded parameter vector. with the final element of the "devs" vector defined as $-\sum_{n-1} v_{i}$, where $v_{i}$ was the ith value of the parameter (or devs) vector, so that the sum over all elements of the devs vector was identically 0 . Penalties were placed on the final element of the devs vector to ensure it was bounded in the same manner as the parameter vector. However, this approach was problematic when initializing the model with the values for the $n-1$ elements that defined the n-element devs vector, the value of the n-th element ( $-\sum_{n-1} v_{i}$ ) was not guaranteed to satisfy the bounds placed on the vector. Thus, this approach was revised to allow specification of all $n$ element values (the $v_{n}=-\sum_{n-1} v_{i}$ constraint was removed) while the likelihood penalty was changed to ensure the sum of the elements was 0 . The new approach also has the advantage that it more closely follows the one used in ADMB to define "devs" vectors. Test runs with both approaches showed no effect on convergence to the MLE solution.

## L. Priors for model parameters

A prior probability distribution can be specified for any element of model parameter. The following distributions are available for use as priors:

| indicator | parameters | constants | description |
| :--- | :--- | :--- | :--- |
| none | none | none | no prior applied |
| ar1_normal | $\mu, \sigma$ | none | random walk with normal deviates |
| cauchy | $x_{0}, \gamma$ | none | Cauchy pdf |
| chisquare | $v$ | none | $\chi^{2}$ pdf |
| constant | min, max | none | uniform pdf |
| exponential | $\lambda$ | none | exponential pdf |
| gamma | $r, \mu$ | none | gamma pdf |
| invchisquare | $v$ | none | inverse $\chi^{2}$ pdf |

| invgamma | $r, \mu$ | none | inverse gamma pdf |
| :--- | :--- | :--- | :--- |
| invgaussian | $\mu, \lambda$ | none | inverse Gaussian pdf |
| lognormal | median, CV | none | lognormal pdf |
| logscale_normal | median, CV | none | normal pdf on ln-scale |
| normal | $\mu, \sigma$ | none | normal pdf |
| scaled_invchisquare | $v, s$ | none | inverse $\chi^{2}$ scaled pdf |
| scaledCV_invchisquare | $v, C V$ | none | inverse $\chi^{2}$ pdf, scaled by CV |
| t | $v$ | none | t distribution |
| truncated_normal | $\mu, \sigma$ | min, max | truncated normal pdf |

## M. Parameters and other information determined outside the model

Several nominal model parameters are not estimated in the model, rather they are fixed to values determined outside the model. These include Tanner crab handling mortality rates for discards in the crab fisheries (32.1\%), the groundfish trawl fisheries (80\%), and the groundfish pot fisheries (50\%), as well the base rate for natural mortality $\left(0.23 \mathrm{yr}^{-1}\right)$. Sex- and maturity-state-specific parameters for individual weight-at-size have also been determined outside the model, based on fits to data collected on the NMFS EBS bottom trawl survey (Daly et al., 2016). Weight-at-size, $w_{x, m, z}$, is given by

$$
w_{x, m, z}=a_{x, m} \cdot z^{b_{x, m}}
$$

where

| sex | maturity state | $\boldsymbol{a}_{\boldsymbol{x}, \boldsymbol{m}}$ | $\boldsymbol{b}_{\boldsymbol{x}, \boldsymbol{m}}$ |
| :--- | :--- | :--- | :--- |
| male | all states | 0.000270 | 3.022134 |
|  | immature | 0.000562 | 2.816928 |
|  | mature | 0.000441 | 2.898686 |

and size is in mm CW and weight is in kg.

## N. OFL calculations and stock status determination

Overfishing level (OFL) calculations and stock status determination for Tanner crab are based on Tier 3 considerations for crab stocks as defined by the North Pacific Fishery Management Council (NPFMC; NPFMC 2016). Tier 3 considerations require life history information such as natural mortality rates, growth, and maturity but use proxies based on a spawner-per-recruit approach for $\mathrm{F}_{\mathrm{MSY}}, \mathrm{B}_{\mathrm{MSY}}$, and MSY because there is no reliable stock-recruit relationship.

Fig. 2. The Fofl harvest control rule.

Equilibrium recruitment is assumed to be
equal to the average recruitment over a selected time period (1982-present for Tanner crab). For Tier 3 stocks, the proxy for $\mathrm{B}_{\mathrm{MSy}}$ is defined as $35 \%$ of longterm (equilibrium) mature male biomass (MMB) for the unfished stock $\left(\mathrm{B}_{0}\right)$. The proxy $\mathrm{F}_{\text {Msy }}$ for Tier 3 stocks is then the directed fishing mortality rate that results in $\mathrm{B}_{35 \%}$ (i.e., $\mathrm{F}_{35 \%}$ ), while the MSY proxy is the longterm total (retained plus discard) catch mortality resulting from fishing at $\mathrm{F}_{\mathrm{msy}}$. The OFL calculation for the upcoming year is based on a sloping
harvest control rule for $\mathrm{FofL}_{\text {( Fig. 2), the directed fishing mortality rate that results in the OFL. If the }}$ "current" MMB (projected to Feb. 15 of the upcoming year under the $\mathrm{F}_{\text {OFL }}$ ) is above $\mathrm{B}_{\text {MSY }}\left(\mathrm{B}_{35 \%}\right.$ ), then $\mathrm{F}_{\text {OFL }}=\mathrm{F}_{\mathrm{MSY}}=\mathrm{F}_{35 \%}$. If the current MMB is between $\beta \cdot B_{M S Y}$ and $\mathrm{B}_{\mathrm{MSY}}$, then $\mathrm{F}_{\text {OFL }}$ is determined from the slope of the control rule. In either of these cases, the OFL is simply the projected total catch mortality under directed fishing at Fofs. If current MMB is less than $\beta \cdot B_{M S Y}$, then no directed fishing is allowed ( $\mathrm{F}_{\mathrm{OFL}}=0$ ) and the OFL is set to provide for stock rebuilding with bycatch in non-directed fisheries. Note that if current MMB is less than $\mathrm{B}_{\text {MSY }}$, then the process of determining FofL is generally an iterative one.

Stock status is determined by comparing "current" MMB with the Minimum Stock Size Threshold (MSST), which is defined as 0.5 xB MSY: if "current" MMB is below the MSST, then the stock is overfished-otherwise, it is not overfished.

## N. 1 Equilibrium conditions

Both OFL calculations and stock status determination utilize equilibrium considerations, both equilibrium under unfished conditions (to determine $\mathrm{B}_{0}$ and $\mathrm{B}_{35 \%}$ ) and under fished conditions (to determine $\mathrm{F}_{35 \%}$ ). For Tier 3 stocks, because there is no reliable stock-recruit relationship, analytical solutions can be found for equilibrium conditions for any fishing mortality conditions. These solutions are described below (the notation differs somewhat from that used in previous sections).

## N.1.1 Population states

The Tanner crab population on July 1 can be characterized by abundance-at-size in four population states:
in- immature new shell crab
io- immature old shell crab
$m n$ - mature new shell crab
mo - mature old shell crab
where each of these states represents a vector of abundance-at-size (i.e., a vector subscripted by size).

## N.1.2 Population processes

The following processes then describe the dynamics of the population over a year:
$S_{1}$ - survival from start of year to time of molting/growth of immature crab, possibly including fishing mortality (a diagonal matrix)
$S_{2}$ - survival after time of molting/growth of immature crab to end of year, possibly including fishing mortality (a diagonal matrix)
$\Phi$ - probability of an immature crab molting ( $\operatorname{pr}(\operatorname{molt} \mid z)$, where $z$ is pre-molt size; a diagonal matrix) ( $\operatorname{pr}(\mathrm{molt} \mid z)$ is assumed to be 1 in TCSAM02).
$\Theta$ - probability that a molt was terminal (pr(molt to maturity|z, molt), where $z$ is post-molt size; a diagonal matrix)
$T$ - size transition matrix (a non-diagonal matrix)
1 - identity matrix
$R$-number of recruits by size (a vector)
The matrices above are doubly-subscripted, and $R$ is singly-subscripted, by size. Additionally, the matrices above (except for the identity matrix) can also be subscripted by population state (in, io, mn, mo) for generality. For example, survival of immature crab may differ between those that molted and those that skipped.

## N.1.3 Population dynamics

The following equations then describe the development of the population from the beginning of one year to the beginning of the next:

$$
\begin{align*}
& i n^{+}=R+S_{2 i n} \cdot\left\{\left(1-\Theta_{i n}\right) \cdot T_{i n} \cdot \Phi_{i n} \cdot S_{1 i n} \cdot i n+T_{i o} \cdot\left(1-\Theta_{i o}\right) \cdot \Phi_{i o} \cdot S_{1 i o} \cdot i o\right\}  \tag{N.1}\\
& i o^{+}=S_{2 i o} \cdot\left\{\left(1-\Phi_{i n}\right) \cdot S_{1 i n} \cdot i n+\left(1-\Phi_{i o}\right) \cdot S_{1 i o} \cdot i o\right\}  \tag{N.2}\\
& m n^{+}=S_{2 m n} \cdot\left\{\Theta_{i n} \cdot T_{i n} \cdot \Phi_{i n} \cdot S_{1 i n} \cdot i n+\Theta_{i o} \cdot T_{i o} \cdot \Phi_{i o} \cdot S_{1 i o} \cdot i o\right\}  \tag{N.3}\\
& m o^{+}=S_{2 m o} \cdot\left\{S_{1 m n} \cdot m n+S_{1 m o} \cdot m o\right\} \tag{N.4}
\end{align*}
$$

where " + " indicates year +1 and all recruits $(R)$ are assumed to be new shell.

## N.1.4 Equilibrium equations

The equations reflecting equilibrium conditions (i.e., $i n^{+}=i n$, etc.) are simply:

$$
\begin{align*}
& i n=R+S_{2 i n} \cdot\left\{\left(1-\Theta_{i n}\right) \cdot T_{i n} \cdot \Phi_{i n} \cdot S_{1 i n} \cdot i n+\left(1-\Theta_{i o}\right) \cdot T_{i o} \cdot \Phi_{i o} \cdot S_{1 i o} \cdot i o\right\}  \tag{N.5}\\
& i o=S_{2 i o} \cdot\left\{\left(1-\Phi_{i n}\right) \cdot S_{1 i n} \cdot i n+\left(1-\Phi_{i o}\right) \cdot S_{1 i o} \cdot i o\right\}  \tag{N.6}\\
& m n=S_{2 m n} \cdot\left\{\Theta_{i n} \cdot T_{i n} \cdot \Phi_{i n} \cdot S_{1 i n} \cdot i n+\Theta_{i o} \cdot T_{i o} \cdot \Phi_{i o} \cdot S_{1 i o} \cdot i o\right\}  \tag{N.7}\\
& m o=S_{2 m o} \cdot\left\{S_{1 m n} \cdot m n+S_{1 m o} \cdot m o\right\} \tag{N.8}
\end{align*}
$$

where $R$ above is now the equilibrium (longterm average) number of recruits-at-size vector.

## N.1.5 Equilibrium solution

The equilibrium solution can be obtained by rewriting the above equilibrium equations as:

$$
\begin{align*}
& i n=R+A \cdot i n+B \cdot i o  \tag{N.9}\\
& i o=C \cdot i n+D \cdot i o  \tag{N.10}\\
& m n=E \cdot i n+F \cdot i o  \tag{N.11}\\
& m o=G \cdot m n+H \cdot m o \tag{N.12}
\end{align*}
$$

where $A, B, C, D, E, F, G$, and $H$ are square matrices. Solving for io in terms of in in eq. 10 , one obtains

$$
\begin{equation*}
\text { io }=\{1-D\}^{-1} \cdot C \cdot \text { in } \tag{N.13}
\end{equation*}
$$

Plugging eq. 13 into 9 and solving for in yields

$$
\begin{equation*}
\text { in }=\left\{1-A-B \cdot[1-D]^{-1} \cdot C\right\}^{-1} \cdot R \tag{N.14}
\end{equation*}
$$

Equations 13 for io and 14 for in can simply be plugged into eq. 11 to yield $m n$ :

$$
\begin{equation*}
m n=E \cdot i n+F \cdot i o \tag{N.15}
\end{equation*}
$$

while eq. 12 can then be solved for mo, yielding:

$$
\begin{equation*}
m o=\{1-H\}^{-1} \cdot G \cdot m n \tag{N.16}
\end{equation*}
$$

where (for completeness):

$$
\begin{align*}
& A=S_{2 i n} \cdot\left(1-\Theta_{i n}\right) \cdot T_{i n} \cdot \Phi_{i n} \cdot S_{1 i n}  \tag{N.17}\\
& B=S_{2 i n} \cdot\left(1-\Theta_{i o}\right) \cdot T_{i o} \cdot \Phi_{i o} \cdot S_{1 i o}  \tag{N.18}\\
& C=S_{2 i o} \cdot\left(1-\Phi_{i n}\right) \cdot S_{1 i n}  \tag{N.19}\\
& D=S_{2 i o} \cdot\left(1-\Phi_{i o}\right) \cdot S_{1 i o}  \tag{N.20}\\
& E=S_{2 m n} \cdot \Theta_{i n} \cdot T_{i n} \cdot \Phi_{i n} \cdot S_{1 i n} \tag{N.21}
\end{align*}
$$

$$
\begin{align*}
& F=S_{2 m n} \cdot \Theta_{i o} \cdot T_{i o} \cdot \Phi_{i o} \cdot S_{1 i o}  \tag{N.22}\\
& G=S_{2 m o} \cdot S_{1 m n}  \tag{N.23}\\
& H=S_{2 m o} \cdot S_{1 m o} \tag{N.24}
\end{align*}
$$

Note that $\Theta$, the size-specific conditional probability of a molt being the terminal molt-to-maturity, is defined above on the basis of post-molt, not pre-molt, size. This implies that whether or not a molt is terminal depends on the size a crab grows into, not the size it at which it molted. An alternative approach would be to assume that the conditional probability of terminal molt is determined by pre-molt size. This would result in an alternative set of equations, but these can be easily obtained from the ones above by simply reversing the order of the terms involving $T$ and $\Theta$ (e.g., the term $\left(1-\Theta_{i n}\right) \cdot T_{i n}$ becomes $T_{i n}$. $\left(1-\Theta_{i n}\right)$ ).

## N. 2 OFL calculations

Because a number of the calculations involved in determining the OFL are iterative in nature, the OFL calculations do not involve automatically-differentiated (AD) variables. Additionally, they are only done after model convergence or when evaluating an MCMC chain. The steps involved in calculating the OFL are outlined as follows:

1. The initial population numbers-at-sex/maturity state/shell condition/size for the upcoming year are copied to a non-AD array.
2. Mean recruitment is estimated over a pre-determined time frame (currently 1982-present).
3. The arrays associated with all population rates in the final year are copied to non-AD arrays for use in the upcoming year.
4. Calculate the average selectivity and retention functions for all fisheries over the most recent 5year period.
5. Determine the average maximum capture rates for all fisheries over the most recent 5-year period.
6. Using the equilibrium equations, calculate $\mathrm{B}_{0}$ for unfished stock $\left(\mathrm{B} 35 \%=0.35 * \mathrm{~B}_{0}\right)$.
7. Using the equilibrium equations, iterate on the maximum capture rate for males in the directed fishery to find the one ( $\mathrm{F}_{35 \%}$ ) that results in the equilibrium $\mathrm{MMB}=\mathrm{B}_{35 \%}$.
8. Calculate "current" MMB under directed fishing at $\mathrm{F}=\mathrm{F}_{35 \%}$ by projecting initial population (1) to Feb. 15.
a. If current $\mathrm{MMB}>\mathrm{B}_{35 \%}, \mathrm{~F}_{\text {OFL }}=\mathrm{F}_{35 \%}$. The associated total catch mortality is OFL.
b. Otherwise
i. set directed F based on the harvest control rule and the ratio of the calculated current MMB to $\mathrm{B}_{35 \%}$
ii. recalculate current MMB
iii. iterate i-iii until current MMB doesn't change between iterations. Then $F_{O F L}=$ $F\left(<F_{35 \%}\right)$ and the OFL is the associated total (retained plus discard) catch mortality.

# Appendix L: Results from the CPT-Recommended Model Scenario 

William T. Stockhausen<br>Alaska Fisheries Science Center<br>15 September 2018<br>THIS INFORMATION IS DISTRIBUTED SOLELY FOR THE PURPOSE OF PREDISSEMINATION PEER REVIEW UNDER APPLICABLE INFORMATION QUALITY GUIDELINES. IT HAS NOT BEEN FORMALLY DISSEMINATED BY NOAA FISHERIES/ALASKA FISHERIES SCIENCE CENTER AND SHOULD NOT BE CONSTRUED TO REPRESENT ANY AGENCY DETERMINATION OR POLICY

## Introduction

The CPT rejected all " 18 " model scenarios put forward by the assessment author. These scenarios were based on revised fishery data which had a substantial impact on estimates of survey catchability and, as a consequence, stock biomass levels. Given the substantial impact the change in data had, the CPT rejected the scenarios based on the revised data because the mechanisms for changes in the results were not fully understood and the data had not been previously reviewed and vetted by the CPT. Consequently, the CPT requested that the assessment author run the 2017 assessment model (17AM) using the data used in that assessment but updated with only the new data for 2017/18 (NMFS survey, retained catch biomass and size compositions from the directed fishery, and total catch biomass and size compositions from the directed fishery and bycatch fisheries). The assessment author was able to comply with this request to the extent of providing results for the maximum likelihood solution; MCMC results for the model scenario were not possible given the time constraints. This model scenario was designated 18AM17. A subset of results from this model scenario are presented in this appendix.

## Management performance

Historical status and catch specifications for eastern Bering Sea Tanner crab from the CPT-recommended model scenario 18AM17.
(a) in 1000's t.

| Year | MSST | Biomass <br> (MMB) | TAC <br> (East + West) | Retained <br> Catch | Total Catch <br> Mortality | OFL | ABC |

b) in millions lbs.

| Year | Tier ${ }^{\text {A }}$ | $\mathrm{B}_{\text {MSY }}{ }^{\text {a }}$ | Current MMB $^{\text {A }}$ | B/BMSY ${ }^{\text {A }}$ | $\begin{gathered} \mathrm{FoFLL}^{\mathrm{A}} \\ \left(\mathrm{yr}^{-1}\right) \end{gathered}$ | Years to define B $_{\text {MSY }^{A}}{ }^{\text {a }}$ | $\begin{gathered} \text { Natural } \\ \text { Mortality } \\ \left(\mathrm{yr}^{-1}\right) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2014/15 | 3 a | 65.74 | 140.66 | 2.14 | 0.61 | 1982-2014 | 0.23 |
| 2015/16 | 3 a | 59.06 | 118.38 | 2.00 | 0.58 | 1982-2015 | 0.23 |
| 2016/17 | 3 a | 56.54 | 99.95 | 1.77 | 0.79 | 1982-2016 | 0.23 |
| 2017/18 | 3 a | 64.30 |  | 2.12 | 0.75 | 1982-2017 | 0.23 |
| 2018/19 | 3 a | 66.78 | 79.26 | 1.08 | 0.74 | 1982-2018 | 0.23 |

A-Calculated from the assessment reviewed by the Crab Plan Team in 20XX of 20XX/(XX+1) or based on the CPT's recommended model for 2018/19.
B-Nominal rate of natural mortality. Actual rates used in the assessment are estimated and may be different.
Current male spawning stock biomass (MMB), as projected for 2018/19, is estimated at 35.95 thousand t . $B_{\text {MSy }}$ for this stock is calculated to be 30.29 thousand t , so MSST is 15.15 thousand t . Because current MMB > MSST, the stock is not overfished. Total catch mortality (retained + discard mortality in all fisheries, using a discard mortality rate of 0.321 for pot gear and 0.8 for trawl gear) in 2017/18 was 2.39 thousand $t$, which was less than the OFL for 2016/17 (25.42 thousand t); consequently overfishing did not occur. The OFL for 2018/19 based on the CPT's recommended scenario (Scenario 18AM17) is 20.87 thousand t. Because there was not time to make MCMC runs, the P* ABC could not be evaluated and thus maxABC could not be determined. In 2014, the SSC adopted a $20 \%$ buffer to calculate ABC for Tanner crab to incorporate concerns regarding model uncertainty for this stock. Based on this buffer, the ABC would be 16.70 thousand $t$.

## Tables and Figures

Selected tables and figures from the original assessment have been updated below for the CPT's recommended scenario 18AM17. The table and figure numbers below do not correspond to those in the original assessment.

## List of Table Captions

Table 1. Comparison of fits to mature survey biomass by sex (in 1000's t) from the 2017 assessment model (17AM) and the CPT's recommended scenario (18AM17).
Table 2. Comparison of estimates of mature biomass-at-mating by sex (in 1000's t) from the 2017 assessment model (17AM) and the CPT's recommended scenario (18AM17).
Table 3. Estimated population size (millions) for females on July 1 of year. from the CPT's recommended scenario (18AM17).
Table 4. Estimated population size (millions) for males on July 1 of year. from the CPT's recommended scenario (18AM17).
Table 5. Comparison of estimates of recruitment (in millions) from the 2017 assessment model (17AM) and the CPT's recommended scenario (18AM17).
Table 6. Comparison of exploitation rates (i.e., catch divided by biomass) from the 2017 assessment model 17AM) and the CPT's recommended scenario (18AM17).10

Table 7. Values required to determine Tier level and OFL for selected model scenarios. These values are presented only to illustrate the effect of incremental changes in the model scenarios. Results from the CPT's recommended model (18AM17) are highlighted in green. Note: the 2017/18 MMB is for July 1, 2018, not at the time of mating.

## 4. Assessment of Pribilof Islands Red King Crab (PIRKC)

## [2017]

B.J. Turnock, C.S. Szuwalski and R.J. Foy<br>Alaska Fishery Science Center<br>National Marine Fishery Service

[NOTE: In accordance with the approved schedule, no assessment was conducted for this stock this year, however, a full stock assessment will be conducted in 2019. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018 specifications]

## Summary of Results

Historical status and catch specifications for Pribilof Islands red king crab ( $t$ ). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

## 2017 Stock assessment and fishery evaluation report for the Pribilof Island red king crab fishery of the Bering Sea and Aleutian Islands regions

B.J. Turnock, C.S. Szuwalski and R.J. Foy<br>Alaska Fishery Science Center<br>National Marine Fishery Service<br>National Oceanic and Atmospheric Administration

## Executive summary

1. Stock: Pribilof Islands red king crab, Paralithodes camtschaticus
2. Catches: Retained catches have not occurred since 1998/1999. Bycatch and discards have been decreasing since 2012/13, and are low relative to the OFL.
3. Stock biomass:
a. According to the random effects model, mature male biomass decreased from 2007 to 2010 and increased during 2011 through 2015, then declined in 2016 and 2017. MMB at mating was estimated to be above $\mathrm{B}_{\text {MSY }}(4,604 \mathrm{t})$ in 2016/17 at $4,788 \mathrm{t}$.
b. Observed survey mature male biomass ( $\geq 120 \mathrm{~mm}$ ) declined from $15,173 \mathrm{t}$ in 2015 to 4,150 t in 2016 and 3,658 t in 2017. Total female biomass declined from 1,898 t in 2016 to 505 t in 2017.
4. Recruitment: No estimates of recruitment are available.
5. Recent management statistics: OFL and ABC in 2011/12 was based on the unweighted 3-year running average. Biomass in 2011/2012 and OFL and ABC from 2012/13 to 2015/16 were based on the weighted 3 -year running average using the inverse of the variance. Biomass (MMB) in $2016 / 17$ and 2017/18 is based on the random effects model (CV=2.24) estimated biomass.

Units in tons

A - Based on the Random effects model (CV=2.24)

The OFL is the total catch OFL for each year. The stock was above MSST in 2016/2017 according to the random effects model $(\mathrm{CV}=2.24)$ at $4,788 \mathrm{t}(\mathrm{MSST}=2,302 \mathrm{t})$. The catch in 2016/17 ( 0.49 t ) was below the $\operatorname{OFL}(1,492 \mathrm{t})$ and the $\operatorname{ABC}(1,096 \mathrm{t})$.

## A. Feb. 15, 2018 fishing at OFL

7. Probability distributions of the OFL for tier 4 methods were generated by bootstrapping values of MMB in the current year with an additional sigma of 0.3 .
8. Basis for ABC : ABCs were identified as the $49^{\text {th }}$ percentile of the distributions of the OFL given a p-star of 0.49 . In addition the ABC was estimated using a $25 \%$ buffer from the OFL as recommended by the CPT and SSC in 2016/17.

## Summary of Major Changes:

1. Management: None.
2. Input data: Survey (2017) and bycatch (2016/17) data were incorporated into the assessment.
3. Assessment methodology: The 3 -year running average and random effects models only are presented in this assessment.
4. Assessment results: Male biomass estimates from the 3 -year running average and a random effects model were fit to survey male biomass $\geq 120 \mathrm{~mm}$ with process error fixed at the value estimated from a simple exponential model and with a prior with mean equal to the process error estimated from the simple exponential model and with $\mathrm{cv}=2.24$ and $\mathrm{cv}=4.0$. Tier 4 control rules are used to estimate MMB at mating, OFL, and ABC for the four models.

## CPT comments May 2017

The CPT recommended that the author continue to develop the random effects model and consider the following for models at the September CPT:

1. Better describe the exponential smoother methods and bring forward one model with the exponential model result as a prior and one model with the process error based on the exponential model fixed.

Included are 3 runs of the random effects model: 1) fixed process error at simple exponential model value, 2 ) with cv of 2.2 in the prior, and 3 ) cv of 4.0 in the prior.
2. Status quo 3-year running average.

Included.
3. Consider fitting to the female biomass to determine if assessing the effects of single sex high biomass tows are informative for determining the observed error relative to process error.

The random effects model did not converge using female biomass. The simple exponential model was fit to female biomass to compare the estimate of process error to fitting male biomass.
4. Consider fitting spatial models (e.g., Thorson et al. 2015) to the survey data that may better account for zero tows and high biomass tows.

Not done in this assessment.

## SSC comments June 2017

There were no comments specific to the Pribilof red king crab assessment by the SSC in June 2017.

## 1. Introduction

1.1 Distribution

Red king crabs, Paralithodes camtschaticus, (Tilesius, 1815) are anomurans in the family Lithodidae and are distributed from the Bering Sea south to the Queen Charlotte Islands and to Japan in the western Pacific (Jensen 1995; Figure 1). Red king crabs have also been introduced and become established in the Barents Sea (Jørstad et al. 2002). The Pribilof Islands red king crab stock is located in the Pribilof District of the Bering Sea Management Area Q. The Pribilof District is defined as Bering Sea waters south of the latitude of Cape Newenham ( $58^{\circ} 39^{\prime} \mathrm{N}$ lat.), west of $168^{\circ} \mathrm{W}$ long., east of the United States - Russian convention line of 1867 as amended in 1991 , north of $54^{\circ} 36^{\prime} \mathrm{N}$ lat. between $168^{\circ} 00^{\prime} \mathrm{N}$ and $171^{\circ} 00^{\prime} \mathrm{W}$ long and north of $55^{\circ} 30^{\prime} \mathrm{N}$ lat. between $171^{\circ} 00^{\prime} \mathrm{W}$. long and the U.S.-Russian boundary (Figure 2).

### 1.2 Stock structure

Populations of red king crab in the eastern Bering Sea (EBS) for which genetic studies have been performed appear to be composed of four stocks: Aleutian Islands, Norton Sound, Southeast Alaska, and the rest of the EBS. Seeb and Smith (2005) reported micro-satellite samples from Bristol Bay, Port Moller, and the Pribilof Islands were divergent from the Aleutian Islands and Norton Sound. A more recent study describes the genetic distinction of Southeast Alaska red king crab compared to Kodiak and the Bering Sea; the latter two being similar (Grant and Cheng 2012).

### 1.3 Life history

Red king crabs reproduce annually and mating occurs between hard-shelled males and soft-shelled females. Red king crabs do not have spermathecae and cannot store sperm, therefore a female must mate every year to produce a fertilized clutch of eggs (Powell and Nickerson 1965). A pre-mating embrace is formed 3-7 days prior to female ecdysis, the female molts, and copulation occurs within hours. The male inverts the female so they are abdomen to abdomen and then the male extends his fifth pair of periopods to deposit sperm on the female's gonopores. Eggs are fertilized after copulation as they are extruded through the gonopores located at the ventral surface of the coxopides of the third periopods. The eggs form a spongelike mass, adhering to the setae on the pleopods where they are brooded until hatching (Powell and Nickerson 1965). Fecundity estimates are not available for Pribilof Islands red king crab, but range from 42,736 to 497,306 for Bristol Bay red king crab (Otto et al. 1990). The estimated size at 50 percent maturity of female Pribilof Islands red king crabs is approximately 102 mm carapace length (CL) which is larger than 89 mm CL reported for Bristol Bay and 71 mm CL for Norton Sound (Otto et al. 1990). Size at maturity has not been determined specifically for Pribilof Islands red king crab males, however, approximately 103 mm CL is reported for eastern Bering Sea male red king crabs (Somerton 1980). Early studies predicted that red king crab become mature at approximately age 5 (Powell 1967; Weber 1967); however, Stevens (1990) predicted mean age at recruitment in Bristol Bay to be 7 to 12 years, and Loher et al. (2001) predicted age to recruitment to be approximately 8 to 9 years after settlement. Based upon a long-term laboratory study, longevity of red king crab males is approximately 21 years and less for females (Matsuura and Takeshita 1990).

Natural mortality of Bering Sea red king crab stocks is poorly known (Bell 2006). Siddeek et al. (2002) reviewed natural mortality estimates from various sources. Natural mortality estimates based upon historical tag-recapture data range from 0.001 to 0.93 for crabs $80-169 \mathrm{~mm}$ CL with natural mortality increasing with size. Natural mortality estimates based on more recent tag-recovery data for Bristol Bay red king crab males range from 0.54 to 0.70 , however, the authors noted that these estimates appear high considering the longevity of red king crab. Natural mortality estimates based on trawl survey data vary from 0.08 to 1.21 for the size range $85-169 \mathrm{~mm}$ CL, with higher mortality for crabs $<125 \mathrm{~mm}$ CL. In an earlier analysis that utilized the same data sets, Zheng et al. (1995) concluded that natural mortality is dome shaped over length and varies over time. Natural mortality was set at 0.2 for Bering Sea king crab stocks (NPFMC 1998) and was changed to 0.18 with Amendment 24.

The reproductive cycle of Pribilof Islands red king crabs has not been established, however, in Bristol Bay, timing of molting and mating of red king crabs is variable and occurs from the end of January through the end of June (Otto et al. 1990). Primiparous (i.e. brooding their first egg clutch) Bristol Bay red king crab females extrude eggs on average 2 months earlier in the reproductive season and brood eggs longer than multiparous (i.e. brooding their second or subsequent egg clutch) females (Stevens and Swiney 2007a, Otto et al. 1990), resulting in incubation periods that are approximately eleven to twelve months in duration (Stevens and Swiney 2007a, Shirley et al. 1990). Larval hatching among red king crabs is relatively synchronous among stocks and in Bristol Bay occurs March through June with peak hatching in May and June (Otto et al. 1990), however larvae of primiparous females hatch earlier than multiparous females (Stevens and Swiney 2007b, Shirley and Shirley 1989). As larvae, red king crabs exhibit four zoeal stages and a glaucothoe stage (Marukawa 1933).

Growth parameters have not been examined for Pribilof Islands red king crabs; however they have been studied for Bristol Bay red king crab. A review by the Center for Independent Experts (CIE) reported that growth parameters are poorly known for all red king crab stocks (Bell 2006). Growth increments of immature southeastern Bering Sea red king crabs are approximately: $23 \%$ at $10 \mathrm{~mm} \mathrm{CL}, 27 \%$ at 50 mm CL, $20 \%$ at 80 mm CL and 16 mm for immature crabs over 69 mm CL (Weber 1967). Growth of males and females is similar up to approximately 85 mm CL, thereafter females grow more slowly than males (Weber 1967; Loher et al. 2001). In a laboratory study, growth of female red king crabs was reported to vary with age; during their pubertal molt (molt to maturity) females grew on average $18.2 \%$, whereas primiparous females grew 6.3\% and multiparous females grew 3.8\% (Stevens and Swiney, 2007a). Similarly, based upon tag-recapture data from 1955-1965 researchers observed that adult female growth per molt decreases with increased size (Weber 1974). Adult male growth increment averages 17.5 mm irrespective of size (Weber 1974).

Molting frequency has been studied for Alaskan red king crabs, but Pribilof Islands specific studies have not been conducted. Powell (1967) reports that the time interval between molts increases from a minimum of approximately three weeks for young juveniles to a maximum of four years for adult males. Molt frequency for juvenile males and females is similar and once mature, females molt annually and males molt annually for a few years and then biennially, triennially and quadrennial (Powell 1967). The periodicity of mature male molting is not well understood and males may not molt synchronously like females who molt prior to mating (Stevens 1990).

### 1.4 Management history

Red king crab stocks in the Bering Sea and Aleutian Islands are managed by the State of Alaska through the federal Fishery Management Plan (FMP) for Bering Sea/Aleutian Islands King and Tanner Crabs (NPFMC 1998). The Alaska Department of Fish and Game (ADF\&G) has not published harvest regulations for the Pribilof district red king crab fishery. The king crab fishery in the Pribilof District began in 1973 with blue king crab Paralithodes platypus being targeted (Figure 3). A red king crab fishery in the Pribilof District opened for the first time in September 1993. Beginning in 1995, combined red and blue king crab

GHLs were established. Declines in red and blue king crab abundance from 1996 through 1998 resulted in poor fishery performance during those seasons with annual harvests below the fishery GHL. The North Pacific Fishery Management Council (NPFMC) established the Bering Sea Community Development Quota (CDQ) for Bering Sea fisheries including the Pribilof Islands red and blue king crab fisheries which was implemented in 1998. From 1999 to present the Pribilof Islands fishery was not open due to low blue king crab abundance, uncertainty with estimated red king crab abundance, and concerns for blue king crab bycatch associated with a directed red king crab fishery. Pribilof Islands blue king crab was declared overfished in September of 2002 and is still considered overfished (see Bowers et al. 2011 for complete management history).

Amendment 21a to the BSAI groundfish FMP established the Pribilof Islands Habitat Conservation Area (Figure 4) which prohibits the use of trawl gear in a specified area around the Pribilof Islands year round (NPFMC 1994). The amendment went into effect January 20, 1995 and protects the majority of crab habitat in the Pribilof Islands area from impacts from trawl gear.

Pribilof Islands red king crab often occur as bycatch in the eastern Bering Sea snow crab (Chionoecetes opilio), eastern Bering Sea Tanner crab (Chionoecetes bairdi), Bering Sea hair crab (Erimacrus isenbeckii), and Pribilof Islands blue king crab fisheries (when there is one). Limited non-directed catch exists in crab fisheries and groundfish pot and hook and line fisheries (see bycatch and discards section below). However, bycatch is currently very low compared to historical levels.

## 2. Data

The standard groundfish discards time series data (updated through 2016/17) were used in this assessment. The crab fishery retained and discard catch time series were updated with 2016/2017 data. The following sources and years of data are available:

| Data source | Years available |
| :--- | :--- |
| NMFS trawl survey | $1975-2017$ |
| Retained catch | $1993-2016 / 17$ |
| Trawl bycatch | $1991-2016 / 17$ |
| Fixed gear bycatch | $1991-2016 / 17$ |
| Pot discards | $1998-2016 / 17$ |

### 2.1 Retained catch

Red king crab were targeted in the Pribilof Islands District from the 1993/1994 season to 1998/1999. Live and deadloss landings data and effort data are available during that time period (Tables 1 and 2), but no retained catch has been allowed since 1999.

### 2.2 Bycatch and discards

Non-retained (directed and non-directed) pot fishery catches are provided for sub-legal males ( $\leq 138 \mathrm{~mm}$ CL), legal males ( $>138 \mathrm{~mm} \mathrm{CL}$ ), and females based on data collected by onboard observers. Catch weight was calculated by first determining the mean weight (g) for crabs in each of three categories: legal nonretained, sublegal, and female. Length to weight parameters were available for two time periods: 1973 to 2009 (males: $\mathrm{A}=0.000361, \mathrm{~B}=3.16$; females: $\mathrm{A}=0.022863, \mathrm{~B}=2.23382$ ) and 2010 to 2013 (males: $\mathrm{A}=0.000403, \mathrm{~B}=3.141$; ovigerous females: $\mathrm{A}=0.003593$, $\mathrm{B}=2.666$; non-ovigerous females: $\mathrm{A}=0.000408$, $\mathrm{B}=3.128$ ). The average weight for each category was multiplied by the number of crabs at that CL , summed, and then divided by the total number of crabs (equation 2).

$$
\begin{equation*}
\text { Weight }(\mathrm{g})=\mathrm{A} * \mathrm{CL}(\mathrm{~mm})^{\mathrm{B}} \tag{1}
\end{equation*}
$$

$$
\begin{equation*}
\text { Mean Weight }(\mathrm{g})=\sum(\text { weight at size } * \text { number at size }) / \sum(\text { crabs }) \tag{2}
\end{equation*}
$$

Finally, weights, discards, and bycatch were the product of average weight, CPUE, and total pot lifts in the fishery. A 20\% handling mortality rate was applied to these estimates (assumed the same as Bristol Bay red king crab).

Historical non-retained catch data are available from 1998/1999 to present from the snow crab, golden king crab (Lithodes aequispina), and Tanner crab fisheries (Table 3) although data may be incomplete for some of these fisheries. Limited observer data exists prior to 1998 for catcher-processor vessels only so nonretained catch before this date are not included here. In 2016/2017 there was no catch of Pribilof Islands red king crab from crab fisheries (Table 3).

### 2.3 Groundfish pot, trawl, and hook and line fisheries

The data through 2016/2017 from the NOAA Fisheries Regional Office (J. Gasper, NMFS, personal communication) assessments of non-retained catch from all groundfish fisheries are included in this SAFE report. Groundfish catches of crab are reported for all crab combined by federal reporting areas and by State of Alaska reporting areas since 2009/2010. Catches from observed fisheries were applied to non-observed fisheries to estimate a total catch. Catch counts were converted to biomass by applying the average weight measured from observed tows from July 2011 to June 2012. Prior to 2011/2012, Areas 513 and 521 were included in the estimate, a practice that likely resulted in an overestimate of the catch of Pribilof Islands red king crab due to the extent of Area 513 into the Bristol Bay District. In 2012/2013 these data were available in State of Alaska reporting areas that overlap specifically with stock boundaries so that the management unit for each stock can be more appropriately represented. To estimate sex ratios it was assumed that the male to female ratio was one. To assess crab mortalities in these groundfish fisheries a $50 \%$ handling mortality rate was applied to pot and hook and line estimates and an $80 \%$ handling mortality rate was applied to trawl estimates.

Historical non-retained groundfish catch data are available from 1991/1992 to present (J. Mondragon, NMFS, personal communication) although sex ratios have not been determined (Table 3). Prior to 1991, data are only available in INPFC reports. Between 1991 and December 2001 bycatch was estimated using the "blend method". The blend method combined data from industry production reports and observer reports to make the best, comprehensive accounting of groundfish catch. For shoreside processors, Weekly Production Reports (WPR) submitted by industry were the best source of data for retained groundfish landings. All fish delivered to shoreside processors were weighed on scales, and these weights were used to account for retained catch. Observer data from catcher vessels provided the best data on at-sea discards of groundfish by vessels delivering to shoreside processors. Discard rates from these observer data were applied to the shoreside groundfish landings to estimate total at-sea discards from both observed and unobserved catcher vessels. For observed catcher/processors and motherships, the WPR and the Observer Reports recorded estimates of total catch (retained catch plus discards). If both reports were available, one of them was selected during the "blend method" for incorporation into the catch database. If the vessel was unobserved, only the WPR was available. From January 2003 to December 2007, a new database structure named the Catch Accounting System (CAS) led to large method change. Bycatch estimates were derived from a combination of observer and landing (catcher vessels/production data). Production data included CPs and catcher vessels delivering to motherships. To obtain fishery level estimates, CAS used a ratio estimator derived from observer data (counts of crab/kg groundfish) that is applied to production/landing information. (See http://www.afsc.noaa.gov/Publications/AFSC-TM/NOAA-TM-AFSC-205.pdf). Estimates of crab are in numbers because the PSC is managed on numbers. There were two issues with this dataset that required estimation work outside of CAS:

1) The estimated number of crab had to be converted to weights. An average weight was calculated using groundfish observer data. This weight was specific to crab year, crab species, and fixed or
trawl gear. This average was applied to the estimated number of crab for crab year by federal reporting area.
2) In some situations, crab estimates were identified and grouped in the observed data to the genus level. These crabs were apportioned to the species level using the identified crab.

From January 2008 to 2012 the observer program changed the method in which they speciate crab to better reflect their hierarchal sampling method and to account for broken crab that in the past were only identified to genus. In addition, haul-level weights collected by the observers were used to estimate the weight of crab through CAS instead of applying an annual (global) weight factor. Spatial resolution was at federal reporting area.

Starting in 2013, a new data set based on the CAS system was made available for January 2009 to present. In 2009 reporting State statistical areas was required on groundfish production reports. The level of spatial resolution in CAS was formally federal reporting area since this the highest spatial resolution at which observer data is aggregated to create bycatch rates. The federal reporting area does not follow crab stock boundaries, in particular for species with small stock areas such as Pribilof Islands or St. Matthew Island stocks, so the new data was provided at the State reporting areas. This method uses ratio estimator (weight crab/weight groundfish) applied to the weight of groundfish reported on production/landing reports. Where possible, this dataset aggregates observer data to the stock area level to create bycatch estimates by stock area. There are instances where no observer data is available and aggregation may go outside of a stock area, but this practice is greatly reduced compared with the pre-2009 data, which at best was at the Federal reporting area level.

Total catch in 2015/16 was 0.32 t and in 2016/17 0.49 t below the 2016/17 OFL $1,492 \mathrm{t}$ and below the ABC of 1,096 t (Tables 3 and 5, Figures 13 and 14). Catch by weight in 2016/17 was $81 \%$ from non-pelagic trawl and $19 \%$ from hook and line fisheries (Table 4).

### 2.4 Catch-at-length

Catch-at-length data are not available for this fishery.

### 2.5 Survey biomass and length frequencies

The 2017 NOAA Fisheries EBS bottom trawl survey results are included in this SAFE report. Data available for estimating the abundance of crab around the Pribilof Islands are relatively sparse. Red king crab have been observed at 35 unique tows in the Pribilof District over the years 1975 to 2017 (in 22 of the 20 nm x 20 nm station grids). The number of stations at which at least one crab was observed in a given year ranges from 0 (in 1975) to 14 (in 2000 and 2013) over the period from 1975-present (Figure 5).

Observed survey biomass estimates for males $\geq 120 \mathrm{~mm}$ are used in the Tier 4 assessment as an estimate of mature male biomass and to estimate the $\mathrm{B}_{\text {MSY }}$ proxy, MMB at mating and in fitting the 3 -yr running average and the random effects model.

Historical survey data are available from 1975 to the present (Tables 6 and 7), and survey data analyses were standardized in 1980 (Stauffer, 2004). Male and female abundance varies widely over the history of the survey time series and uncertainty around area-swept estimates of abundance are large due to relatively low sample sizes (Table 7). Male crabs were observed at 9 of 35 stations in the Pribilof District during the 2015 NMFS survey (Figure 6); female crabs were observed at 5 (Figure 7). Two (possibly three) cohorts can be seen moving through the length frequencies over time (Figures 8 and 9). Numbers at length vary dramatically from year to year, but the cohorts can nonetheless also be discerned in these data (Figure 10 and Figure 11).

The centers of distribution for both males and females have moved within a 40 nm by 40 nm region around St. Paul Island. The center of the red king crab distribution moved to within 20 nm of the northeast side of St. Paul Island as the population abundance increased in the 1980's and remained in that region until the 1990's. Since then, the centers of distribution have been located closer to St. Paul Island the exception of 2000-2003 located towards the north east.

Survey abundance for males $\geq 105 \mathrm{~mm}$ declined from 3,662,609 in 2015 to 1,807,323 in 2016 and again in 2017 to $1,158,383$ (Table 6). Female biomass (all sizes) declined from 3,859 t in 2015 to $1,898 \mathrm{t}$ in 2016 and declined further in 2017 to 505 t . Survey biomass for males $\geq 120 \mathrm{~mm}$ declined from $15,173 \mathrm{t}$ in 2015 to $4,150 \mathrm{t}$ in 2016 and declined further in 2017 to $3,658 \mathrm{t}$ (Table 8).

## 3. Analytical approaches

### 3.1 History of modeling

An inverse-variance weighted 3-year running average of male biomass ( $\geq 120 \mathrm{~mm}$ ) based on densities estimated from the NMFS summer trawl survey has been used in recent years to set allowable catches. The natural mortality rate has been used as a proxy for the fishing mortality at which maximum sustainable yield occurs ( $\mathrm{F}_{\mathrm{MSY}}$ ) and target biomasses are set by identifying a range of years over which the stock was thought to be near $\mathrm{B}_{\mathrm{MSY}}$ (i.e. a tier 4 control rule).

In 2017, biomass and derived management quantities are estimated by a 3-yr running-average method and a random effects method. The Tier 4 harvest control rule (HCR) is applied to the running-average and random effects estimates of mature male biomass ( $\geq 120 \mathrm{~mm}$ ). The current year biomass estimate was projected forward to February 15 for use in the OFL control rule to estimate the OFL and ABC. The B BSY proxy for both the $3-\mathrm{yr}$ running average and the random effects model was estimated as the average of the 1991/92 to 2016/17 observed survey data projected forward to February 15, removing the observed catch.

### 3.2 Model descriptions

### 3.2.1. Running average

A 3 year running average of male biomass ( $\geq 120 \mathrm{~mm}$ ) at survey time was calculated using the weighted average with weights being the inverse of the variance,

$$
\begin{equation*}
B W R A_{t}=\frac{\sum_{t-1}^{t+1} \frac{M M B_{t}}{\sigma_{t}^{2}}}{\sum_{t-1}^{t+1} \frac{1}{\sigma_{t}^{2}}} \tag{4}
\end{equation*}
$$

Where,

$$
\begin{array}{cl}
M M B_{t} & \text { Estimated male biomass }(\geq 120 \mathrm{~mm}) \text { from the survey data } \\
\sigma_{t}^{2} & \text { The variance associated with the estimate of MMB in year } \mathrm{t}
\end{array}
$$

$w_{t}$ is calculated as the variance of the $\log$ (biomass) using the CVs of the estimates of MMB from the survey provided by the Kodiak lab:

$$
\begin{equation*}
w_{t}=\ln \left(\left(C V_{t}^{M M B}\right)^{2}+1\right) \tag{5}
\end{equation*}
$$

Where,

## $C V_{t}^{M M B} \quad$ Coefficient of variation associated with the estimate of

 MMB at time $t$
### 3.2.2 Random Effects Model

A random effects model was fit to the survey male biomass ( $\geq 120 \mathrm{~mm}$ ) for estimation of current biomass, MMB at mating, OFL and ABC (Model developed for use in NPFMC groundfish assessments). The model uses the CVs as calculated for the $3-\mathrm{yr}$ running average. The random effects model was fit to the $\log$ of survey biomass at the time of the survey. The likelihood equation for the random effects model is,

$$
\sum_{i=1}^{y r s}\left\{0.5\left(\log \left(2 \pi \sigma_{i}^{2}\right)+\left(\frac{\left(\widehat{B}_{i}-B_{i}\right)^{2}}{\sigma_{i}^{2}}\right)\right)\right\}+\sum_{t=2}^{y r s}\left\{0.5\left(\log \left(2 \pi \sigma_{p}^{2}\right)+\left(\frac{\left(\widehat{B}_{t}-\widehat{B}_{t-1}\right)^{2}}{\sigma_{p}^{2}}\right)\right)\right\}
$$

Where,
$B_{\mathrm{i}}$ is the log of observed biomass in year i ,
$\widehat{B_{l}}$ is the model estimated log biomass in year t ,
$\sigma_{i}^{2}$ is the variance of observed log biomass in year i ,
$\sigma_{p}^{2}$ is the variance of the deviations in log survey biomass between years (i.e. process error variance), $\sigma_{p}^{2}$ was estimated as $e^{(2 \lambda)}$, where $\lambda$ is a parameter estimated in the random effects model and,

Yrs is the number of years of survey biomass values.
In the case where the random effects model does not converge due to high observation errors, an estimate of the process error is necessary to use as a prior or to fix in the model (P. Spencer pers. comm., Figure 15). A simple exponential model can be used to estimate the ratio of observation error to process error in a time series,
$\hat{z}_{t}=\alpha y_{t}+\alpha(1-\alpha) y_{t-1}+\alpha(1-\alpha)^{2} y_{t-2}+\alpha(1-\alpha)^{3} y_{t-3}+\cdots$,
Where,
$\hat{z}_{0}$ is set equal to $y_{0}$, the log of observed biomass in the first year,
$y_{t}$ is the log of observed biomass in year t and,
$\alpha$ is the parameter estimated in the model which ranges from 0 to 1 .
An estimate of the ratio of observation error $\left(\sigma_{o}^{2}\right)$ to process error $\left(\sigma_{p}^{2}\right)$ (log scale) is,

$$
\frac{\sigma_{o}^{2}}{\sigma_{p}^{2}}=\frac{(1-\alpha)}{\alpha^{2}}
$$

An estimate of $\lambda$ to use as a prior in the random effects model is,

$$
\lambda=0.5 \log \left(\sigma_{p}^{2}\right)
$$

The variance of $\alpha$ is an output of the arima function in R which was used to fit the simple exponential model. A bootstrap using the logit distribution on $\alpha$ was used to approximate the variance of $\lambda$ for use in the prior that is added to the likelihood in the random effects model,

$$
0.5 \frac{\left(\lambda-\lambda_{p}\right)^{2}}{\sigma_{\lambda}^{2}}
$$

Where,
$\lambda_{p}$ is the prior estimate of $\lambda$ from the simple exponential model
$\sigma_{\lambda}^{2}$ is the variance of $\lambda_{p}$ estimated from the parametric bootstrap.
The random effects model was run with $\lambda$ fixed at the value estimated from the simple exponential model and with $\lambda$ estimated adding the prior likelihood into the random effects model.

## 4. Model Selection and Evaluation

The running average method with a tier 4 HCR was selected in 2016 by the SSC as the model to determine the OFL and ABC based on concerns around different trends over the last decade between the integrated model and the running average and the lack of fit of the integrated model to survey abundance data. Four assessment methods are presented here for comparison: a running average with a tier 4 HCR , a random effects model with fixed $\lambda$, and a random effects model with a prior likelihood component added for $\lambda$.

### 5.0 Results

### 5.1 Tier 4

Survey mature male biomass ( $\geq 120 \mathrm{~mm}$ ) declined from 4,150 t in 2016 to $3,658 \mathrm{t}$ in 2017. The 3 - yr running average estimate of mature male biomass ( $\geq 120 \mathrm{~mm}$ ) was $3,888 \mathrm{t}$ in 2017 at the survey time, while the random effects model with process error fixed estimate was $4,163 \mathrm{t}$ (Table 8 and Figure 16). The simple exponential model estimated $\alpha=0.705$ with a standard deviation of 0.134 , which results in $\sigma_{p}^{2}=0.643$ and a $\mathrm{CV}=2.24$ (estimated from bootstrap). When process error is estimated with a prior in the random effects model with a $\mathrm{CV}=2.24$, the 2017 biomass estimate was estimated at $4,307 \mathrm{t}$. When process error is estimated with a prior in the random effects model with a CV $=4.0$, the 2017 biomass estimate was $4,633 \mathrm{t}$ and results in more smoothing of the estimates (Figure 16). The random effects model was also fit with a CV on the prior of 5.0 which resulted in the model not converging. The random effects model did not converge when trying to fit female biomass due to high observed variances similar to male biomass. The increase in CV in the prior on $\lambda$ results in lower process error and a smoother fit to biomass. The parameters and process error for the random effects models were,

| Random effects <br> Model | $\lambda$ | $\sigma_{p}^{2}$ | CV |
| :--- | :---: | :--- | :--- |
| $\lambda$ fixed | -0.221 | 0.643 | NA |
| with prior on $\lambda$ | -0.364 | 0.483 | 2.24 |
| with prior on $\lambda$ | -0.640 | 0.278 | 4 |

The simple exponential model fit to female mature biomass ( $\geq 90 \mathrm{~mm}$ ) estimated process error at 0.280 , which is lower than the process error estimated at 0.643 for the mature male biomass ( $\geq 120 \mathrm{~mm}$ ), however, similar to process error estimated in the random effects model ( 0.278 ) with prior on $\lambda=-0.221$ and $\mathrm{CV}=4$.

MMB at mating on February 15, 2017 (2016/17 crab year) was estimated at 3,681 tor the observed survey, $6,445 \mathrm{t}$ for the $3-\mathrm{yr}$ weighted average, $4,683 \mathrm{t}$ for the random effects model fixed process error, $4,788 \mathrm{t}$ for the random effects model $\mathrm{cv}=2.24$ and $4,961 \mathrm{t}$ for the random effects model $\mathrm{cv}=4.0$ (Table 9 and Figure 17). The estimation of process error in the random effects model with a $\mathrm{cv}=4.0$ results in a smoother fit to biomass than the 3 year running average or the random effects models with lower cv or fixed process error. The 3 -yr running average biomass estimate in 2016 is the weighted average of survey biomass in 2015, 2016 and 2017. The high survey biomass in 2015 results in a larger estimated biomass in 2016 (and the projected February 15, 2017 biomass) than for the random effects models which take into account the whole time series. The use of the 3 -yr running average can be thought of as imposing a prior on smoothness by using 3 biomass values for each estimate. Using more biomass values for the average would result in a smoother fit to the data as well as using the random effects model with a weaker prior. The CVs of the survey biomass range from 0.36 to 1.0 with an average of 0.67 .

## 6. Calculation of reference points

### 6.1 Tier 4 OFL and $B_{M S Y}$

Natural mortality was used as a proxy for $\mathrm{F}_{\text {MSY }}$ and a proxy for $\mathrm{B}_{\text {MSY }}$ was calculated by averaging the biomass of a predetermined period of time thought to represent the time when the stock was at $\mathrm{B}_{\text {MSY }}$ in the tier 4 HCR. The OFL was calculated by applying a fishing mortality determined by equation 4 to the mature male biomass at the time of fishing.

$$
F_{O F L}= \begin{cases}\text { Bycatch only } & \text { if } \frac{B_{\text {cur }}}{B_{M S Y \text { proxy }}} \leq \beta  \tag{4}\\ \frac{\gamma M\left(\frac{B_{\text {cur }}}{B_{M S Y} \text { proxy }}-\alpha\right)}{1-\alpha} & \text { if } \beta<\frac{B_{\text {cur }}}{B_{M S Y \text { proxy }}}<1 \\ \gamma M & \text { if } B_{\text {cur }}>B_{M S Y \text { proxy }}\end{cases}
$$

Where,

| $B_{\text {cur }}$ | Estimated mature male biomass projected to time of mating fishing at the OFL |
| :---: | :--- |
| $B_{M S Y}$ proxy | Average mature male biomass over the years 1991-present |
| $M$ | Natural mortality |
| $\alpha$ | Determines the slope of the descending limb of the HCR (0.05) |
| $\beta$ | Fraction of B $_{\text {MSY proxy }}$ below which directed fishing mortality is zero (here set to |
|  | $0.25)$ |

### 6.3 Acceptable biological catches

An acceptable biological catch (ABC) was estimated below the OFL by a proportion based a predetermined probability that the ABC would exceed the $\mathrm{OFL}\left(\mathrm{P}^{*}\right)$. Currently, $\mathrm{P}^{*}$ is set at 0.49 and represents a proportion of the OFL distribution that accounts for within assessment uncertainty $\left(\sigma_{w}\right)$ in the OFL to establish the maximum permissible $\mathrm{ABC}\left(\mathrm{ABC}_{\text {max }}\right)$. Any additional uncertainty outside of the assessment methods ( $\sigma_{b}$ ) will be considered as a recommended ABC below $\mathrm{ABC}_{\text {max }}$. Additional uncertainty will be included in the application of the ABC by adding the uncertainty components as $\sigma_{\text {total }}=\sqrt{\sigma_{b}^{2}+\sigma_{w}^{2}}$.

### 6.4 Specification of the distributions of the OFL used in the ABC

A distribution for the OFL associated with estimates of MMB from the running average method was constructed by bootstrapping values of $\mathrm{MMB}_{\text {mating }}$ (assuming that MMB is log-normally distributed) and calculating the OFL according to equation 4. Additional uncertainty ( $\sigma_{b}$ ) equal to 0.3 was added when bootstrapping values of MMB while calculating the distribution for the OFL for the tier 4 HCR. The posterior distribution for the OFL generated from the integrated assessment was used for determining the ABC.

### 6.6 Tier 4 Reference points and OFL

$\mathrm{B}_{\text {MSY }}$ was estimated at $5,502 \mathrm{t}$ using observed male survey biomass ( $\geq 120 \mathrm{~mm}$ ) from 1991/92 to 2016/17. Projected MMB for 2017/18 (on February 15, 2018 removing the OFL) calculated from the 3-year running average was $3,139 \mathrm{t}$ ( $57 \%$ of $\mathrm{B}_{\text {MSY }}$ ). Bmsy for the random effects models was estimated from model output from 1991/92 to 2016/17. The random effects model (RE) with fixed process error estimated projected MMB for 2017/18 at $3,274 \mathrm{t}\left(69 \%\right.$ of $\mathrm{B}_{\mathrm{MSY}}=4,711 \mathrm{t}$ ). The RE with $\mathrm{CV}=2.24$ estimated 2017/18 MMB at $3,364 \mathrm{t}\left(73 \%\right.$ of $\left.\mathrm{B}_{\mathrm{MSY}}=4,604 \mathrm{t}\right)$ and the RE with $\mathrm{CV}=4.0$ at $3,563 \mathrm{t}\left(67 \%\right.$ of $\left.\mathrm{B}_{\text {MSY }}=4,397 \mathrm{t}\right)$. The 2017/18 OFL for the 3 -yr weighted average was 330 t , from the random effects model (RE) with fixed process error at 442 t , the RE with $\mathrm{CV}=2.24$ at 482 t and the RE with $\mathrm{CV}=4.0$ at 573 t (see Table in item 6 of the executive summary).

### 6.7 Recommended ABCs

The ABC estimated using a $p^{*}$ of 0.49 with an additional sigma of 0.30 was 319 t for the 3 -yr running average, 428 t for the random effects model (RE) with fixed process error, 467 t for the RE with $\mathrm{CV}=2.24$ and 554 t for the RE with $\mathrm{CV}=4.0$. The ABC with a $25 \%$ buffer ( $\mathrm{ABC}=\mathrm{OFL} * 0.75$ ) (recommended by the CPT and SSC in 2015) was 248 t for the 3 -yr running average, 332 t for the random effects model (RE) with fixed process error, 362 t for the RE with $\mathrm{CV}=2.24$ and 429 t for the RE with $\mathrm{CV}=4.0$ (see Table in item 6 of the executive summary).

### 6.8 Variables related to scientific uncertainty in the OFL probability distribution

Uncertainty in estimates of stock size and OFL for Pribilof Islands red king crab was relatively high due to small sample sizes. The coefficient of variation for the estimate of mature male biomass for 2017 was 0.65 and has ranged between 0.36 and 0.92 since the 1991 peak in numbers. These CVs were calculated by assuming the data are Poisson distributed, but the data are overdispersed. Using a negative binomial (or other distribution that can allow for overdispersion) would increase the CVs. Growth and survey selectivity were estimated within the integrated assessment (and therefore uncertainty in both processes is accounted for in the posterior distributions), but maturity, survey catchability, fishery selectivity, and natural mortality were fixed. $\mathrm{F}_{\text {MSY }}$ was assumed to be equal to natural mortality and $\mathrm{B}_{\text {MSY }}$ was somewhat arbitrarily set to the average MMB over a predetermined range of years for tier 4 HCRs; both of which were assumptions that had a direct impact on the calculated OFL. Sources of mortality from discard in the crab pot fishery and the fixed gear fishery were not included in the integrated assessment because of a lack of length data to apportion removals correctly. Including these sources of mortality may alter the estimated MMB.

### 6.9 Author Recommendation

In the foreseeable future, low sample size will be a problem for the Pribilof Island red king crab, so extra precaution should be taken given the uncertainty associated with MMB estimates. In this respect, the tier 4 HCR is more precautionary in that it sets a higher MSST and a lower $\mathrm{F}_{\text {OFL, }}$ OFL, and ABC for a given MMB (Turnock, et al. 2016). If there is a particularly high estimate of MMB from the survey (often associated with high variance-see 2015 for an example), the biomass and OFL can be higher for the 3 -yr running average than the random effects models. The random effects model can be useful in these years because it smooths over fluctuations in estimates of biomass and numbers, which often appear to be the
result of measurement error The authors recommendation is to use the random effects model with $\mathrm{CV}=2.24$ in the prior on process error as this results in a more smooth fit to biomass and would be less influenced by fluctuations in biomass than the 3 -yr running average model. The $\mathrm{CV}=2.24$ is estimated from the variance of the parameter estimated from the simple exponential model while the $\mathrm{CV}=4.0$ is arbitrary and was used as a sensitivity.

Females and males experienced similar increases in abundance in the early 1990s, and only in recent years did trends in their abundances deviate from previously correlated trajectories. This suggests that some population process (e.g. natural mortality or catchability) has changed for males or females, but it is difficult to say if the change in trends was a result of a population process for females or for males (or both) changing. It is generally inadvisable to invoke time-varying population processes within an assessment for the sake of improving fits without a hypothesis behind the changes and data to corroborate it.

## 7. Data gaps and research priorities

The largest data gap is the number of observations from which the population size and biomass is extrapolated. Catch-at-length data for the trawl fishery would allow trawl fishery selectivity to be estimated and discard mortality specific to PIRKC to be incorporated into the integrated model. Simulation studies designed to prioritize research on population processes for which additional information would be beneficial in achieving more accurate estimates of management quantities could be useful for this stock (e.g. Szuwalski and Punt, 2012). Research on the probability of molting at length for males would allow the use of data specific to PIRKC in specifying molting probability in the assessment. Research aimed at the catchability and availability of PIRKC may shed some light on divergent changes in abundance in recent years.

## 8. Ecosystem Considerations

The impact of a directed fishery for Pribilof Islands red king crab on the population of Pribilof island blue king crab will likely continue to be the largest ecosystem consideration facing this fishery and preclude the possibility of a directed fishery for red king crab. Linking changes in productivity as seen in the 1980s with environmental influences is a potential avenue of research useful in selecting management strategies for crab stocks around the Pribilof Islands (e.g. Szuwalski and Punt, 2013a). It is possible that the large year class in the mid-1980s reflected changing environmental conditions, similar to proposed relationships between the Pacific Decadal Oscillation snow crab recruitment in the EBS (Szuwalski and Punt, 2013b). Ocean acidification also appears to have a large detrimental effect on red king crab (Long et al., 2012), which may impact the productivity of this stock in the future.

## 12. Figures

Figure 1. Red king crab distribution.

Figure 2. King crab registration area Q (Bering Sea) showing the Pribilof District.

Figure 3. Historical harvests and GHLs for Pribilof Island blue (diamonds) and red king crab (triangles) (Bowers et al. 2011).

Figure 4. The shaded area shows the Pribilof Islands Habitat Conservation area.

Figure 5. Total number of observed crab (top) and the number of tows that reported observations of crab $($ female $=$ dashed line, male $=$ solid line $)$ from 1976-2017.

Figure 6. Male red king crab relative density by station in the Pribilof Island district in 2017. Bars represent the relative magnitude of the density calculated from the NMFS trawl survey.

Figure 7. Female red king crab relative density by station in the Pribilof Island district in 2017. Bars represent the relative magnitude of the density calculated from the NMFS trawl survey.

Figure 8. Observed length frequencies (proportions sum to 1.0 ) by 5 mm length classes of Pribilof Islands male red king crab (Paralithodes camtschaticus) from 1975 to 2017.

Figure 9. Observed length frequencies (proportions sum to 1.0 ) by 5 mm length classes of Pribilof Islands female red king crab (Paralithodes camtschaticus) from 1975 to 2017.

Figure 10. Observed numbers at length by 5 mm length classes of Pribilof Islands male red king crab (Paralithodes camtschaticus) from 1975 to 2017.

Figure 11. Observed numbers at length by 5 mm length classes of Pribilof Islands female red king crab (Paralithodes camtschaticus) from 1975 to 2017.

Figure 12. Modes of the length frequency distribution for males and females plotted for two time periods over which two cohorts were observed to move through the population. Growth per molt calculated from the modes from the length frequencies with fitted linear relationship (bottom).

Figure 13. Directed fishery retained catch.

Figure 14. Total bycatch for Pribilof red king crab.

## From Spencer presentation at Wakefield 2015

A simple exponential smoothing model can give information on the ratio of variances

$$
\hat{z}_{t}=(\alpha) y_{t}+(1-\alpha)\left[\alpha y_{t-1}+\alpha(1-\alpha) y_{t-2}+\alpha(1-\alpha)^{2} y_{t-3}+\ldots\right]
$$

Figure 15. Using a simple exponential smoothing model to estimate the variance ratio of observation error and process error.

## Pribilof Red King Crab

Figure 16. Mature male biomass $(\mathrm{t})(\geq 120 \mathrm{~mm})$ at the time of the survey. Lines are the fit for the 3 year weighted average, the random effects model with process error fixed ( 0.643 ), the random effects model with cv on prior of 2.24 , the random effects model with cv on prior of 4.0 and the simple exponential model.

## Pribilof Red King Crab

Figure 17. MMB at mating ( t ) for the 3 year weighted average, the random effects model with process error fixed, the random effects model with cv on prior of 2.24 and the random effects model with cv on prior of 4.0. Bmsy is the average of the survey biomass from 1991/92 to 2016/17. MSST is $50 \%$ of Bmsy.

# 5. Assessment of Pribilof Islands Blue King Crab (PIBKC) 

## [2017]

William T. Stockhausen<br>Alaska Fisheries Science Center<br>National Marine Fisheries Service

[NOTE: In accordance with the approved schedule, no assessment was conducted for this stock this year, however, a full stock assessment will be conducted in 2019. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018 specifications]

## Summary of Results

Historical status and catch specifications for Pribilof Islands blue king crab (t). Shaded values are new estimates or projections based on the current assessment. Other table entries are based on historical assessments and are not updated except for total and retained catch.

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2014 / 15$ | 2,055 | 344 | Closed | 0 | 0.07 | 1.16 | 0.87 |

12 Size frequencies from the annual NMSF bottom trawl survey for male Pribilof Islandsblue king crab by 5 mm length bins. The top row shows the entire time series, thebottom shows the size compositions since 1995.47
$13 \quad F_{O F L}$ Control Rule for Tier 4 stocks under Amendment 24 to the BSAI King and Tanner Crabs fishery management plan. Directed fishing mortality is set to 0 below $\beta$ ( $=0.25$ ). ..... 48

## Executive Summary

1. Stock: Pribilof Islands blue king crab (PIBKC), Paralithodes platypus.
2. Catches: Retained catches have not occurred since 1998/1999. Bycatch has been relatively small in recent years. No bycatch mortality was observed in 2016/17 in the crab (e.g., Tanner crab, snow crab) fisheries that incidentally take PIBKC. Bycatch mortality for PIBKC in these
fisheries was 0.166 t ( 0.0004 million lbs) in $2015 / 16$, but this was the first non-zero bycatch mortality in other crab fisheries since 2010/11. Most bycatch mortality for PIBKC occurs in the BSAI groundfish fixed gear (pot and hook-and-line) fisheries (5-year average: 0.048 t ) and trawl fisheries (5-year average: 0.309 t). In $2016 / 17$, the estimated PIBKC bycatch mortality was 0.018 t in the groundfish fixed gear fisheries and 0.364 t in the groundfish trawl fisheries.
3. Stock biomass: Stock biomass decreased between the 1995 and 2008 surveys, and continues to fluctuate at low abundances in all size classes. Any short-term trends are questionable given the high uncertainty associated with recent survey results.
4. Recruitment: Recruitment indices are not well understood for Pribilof Islands blue king crab. Pre-recruits may not be well-assessed by the survey, but have remained consistently low in the past 10 years.
5. Management performance: The stock is below MSST and consequently is overfished. Overfishing did not occur. The following results are based on determining $B_{M S Y} / \mathrm{MSST}$ by averaging the MMB-at-mating time series estimated using the smoothed survey data from a random effects model; the current $(2017 / 18)$ MMB-at-mating is also based on the smoothed survey data. [Note: MSST changed substantially between $2013 / 14$ and 2014/15 as a result of changes to the NMFS EBS trawl survey dataset used to calculate the proxy $B_{M S Y}$. MSST has changed slightly since 2014/15 due to small differences in the random effects model results with the addition of each new year of survey data.]

Table 1: Management performance, all units in metric tons. The OFL is a total catch OFL for each year.

| Year | MSST | Biomass <br> $\mathbf{( M M B}_{\text {mating }}$ | TAC | Retained <br> Catch | Total Catch <br> Mortality | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| $2016 / 17$ | -- | 0.507 A | -- | -- | -- | 0.0026 | 0.002 |

6. Basis for the 2017/18 OFL: The OFL was based on Tier 4 considerations. The ratio of estimated $2016 / 17$ MMB-at-mating to $B_{M S Y}$ is less than $\beta$ (0.25) for the $F_{O F L}$ Control Rule, so directed fishing is not allowed. As per the rebuilding plan (NPFMC, 2014a), the OFL is based on a Tier 5 calculation of average bycatch mortalities between 1999/2000 and 2005/2006, which is a time period thought to adequately reflect the conservation needs associated with this stock and to acknowledge existing non-directed catch mortality. Using this approach, the OFL was determined to be 1.16 t for 2017/18. The following results are based on determining $B_{M S Y} /$ MSST by averaging the MMB-at-mating time series estimated using the smoothed survey data from a random effects model; the current (2017/18) MMB-at-mating is also based on the smoothed survey data.

7. Probability density function for the OFL: Not applicable for this stock.
8. $A B C$ : The ABC was calculated using a $25 \%$ buffer on the OFL, as in the previous assessments since 2015. The ABC is thus $0.87 \mathrm{t}(=0.25 \times 1.16 \mathrm{t})$.
9. Rebuilding analyses results summary: In 2009, NMFS determined that the PIBKC stock was not rebuilding in a timely manner and would not meet a rebuilding horizon of 2014. A preliminary assessment model developed by NMFS (not used in this assessment) suggested that rebuilding could occur within 50 years due to random recruitment (NPFMC, 2014a). Subsequently, Amendment 43 to the King and Tanner Crab Fishery Management Plan (Crab

FMP) and Amendment 103 to the Bering Sea and Aleutian Islands Groundfish FMP (BSAI Groundfish FMP) to rebuild the PIBKC stock were adopted by the Council in 2012 and approved by the Secretary of Commerce in early 2015. The function of these amendments is to promote bycatch reduction on PIBKC by closing the Pribilof Islands Habitat Conservation Zone to pot fishing for Pacific cod. No pot fishing for Pacific cod occurred within the Pribilof Islands Habitat Conservation Zone in 2015/16.

## A. Summary of Major Changes:

## 1. Management

In 2002, NMFS notified the NPFMC that the PIBKC stock was overfished. A rebuilding plan was implemented in 2003 that included the closure of the stock to directed fishing until the stock was rebuilt. In 2009, NMFS determined that the PIBKC stock was not rebuilding in a timely manner and would not meet the rebuilding horizon of 2014. Subsequently, Amendment 43 to the Crab FMP and Amendment 103 to the BSAI Groundfish FMP to rebuild the PIBKC stock were adopted by the Council in 2012 and approved by the Secretary of Commerce in early 2015. Amendment 103 closed the Pribilof Islands Habitat Conservation Zone to pot fishing for Pacific cod to promote bycatch reduction on PIBKC. Amendment 43 amended the prior rebuilding plan to incorporate new information on the likely rebuilding timeframe for the stock, taking into account environmental conditions and the status and population biology of the stock. No pot fishing for Pacific cod has occurred within the Pribilof Islands Habitat Conservation Zone since 2015/16.

## 2. Input data

Retained and discard catch time series were updated with 2015/2016 data from the crab and groundfish fisheries. Abundance and biomass for PIBKC in the annual summer NMFS EBS bottom trawl survey were updated for the 2016 survey.

## 3. Assessment methodology

There are no changes from the 2016/17 assessment. The Tier 4 approach used in this assessment for status determination, based on smoothing the raw survey biomass time series using a random effects model, is identical to that adopted by the CPT and SSC in 2015 and used in the 2015 and 2016 assessments (Stockhausen, 2015, 2016).

## 4. Assessment results

Total catch mortality in 2016/17 was 0.38 t , which DID NOT exceed the OFL (1.16 t). Consequently, overfishing DID NOT occur in 2016/17. The projected MMB-at-mating for 2017/18 decreased slightly from that in 2016/17 but remained below the MSST. Consequently, the stock remains overfished and a directed fishery is prohibited in 2017/18. The OFL, based on average catch, and ABC are identical to last year's values.

## B. Responses to SSC and CPT Comments

## CPT comments September 2015:

Specific remarks pertinent to this assessment
Use results from the random effects smoothing model to calculate both $B_{M S Y}$ and current $B$ for status determination.

Responses to CPT Comments:
Results from the random effects model were used to calculate both $B_{M S Y}$ and current $B$ for status determination.

SSC comments October 2015:
Specific remarks pertinent to this assessment
none

## CPT comments May 2016:

Specific remarks pertinent to this assessment
none

SSC comments June 2016:
Specific remarks pertinent to this assessment
none

## CPT comments September 2016:

Specific remarks pertinent to this assessment
Apply the same handling mortality to bycatch of PIBKC by fixed gear as is applied to other king crab stocks (0.2).

Responses to CPT Comments:
This assessment uses 0.2 as the handling mortality applied to all fixed gear bycatch.

SSC comments October 2016:
Specific remarks pertinent to this assessment
none

## CPT comments May 2017:

Specific remarks pertinent to this assessment none

SSC comments June 2017:
Specific remarks pertinent to this assessment none

## C. Introduction

## 1. Stock

Pribilof Islands blue king crab (PIBKC), Paralithodes platypus.

## 2. Distribution

Blue king crab are anomurans in the family Lithodidae, which also includes the red king crab (Paralithodes camtschaticus) and golden or brown king crab (Lithodes aequispinus) in Alaska. Blue king crabs are found in widely-separated populations across the North Pacific (Figure 1). In the western Pacific, blue king crabs occur off Hokkaido in Japan and isolated populations have been observed in the Sea of Okhotsk and along the Siberian coast to the Bering Straits. In North America, they are found in the Diomede Islands, Point Hope, outer Kotzebue Sound, King Island, and the outer parts of Norton Sound. In the remainder of the Bering Sea, they are found in the waters off St. Matthew Island and the Pribilof Islands. In more southerly areas, blue king crabs are found in the Gulf of Alaska in widely-separated populations that are frequently associated with fjord-like bays (Figure 1). The insular distribution of blue king crab relative to the similar but more broadly distributed red king crab is likely the result of post-glacial-period increases in water temperature that have limited the distribution of this cold-water adapted species (Somerton 1985). Factors that may be directly responsible for limiting the distribution include the physiological requirements for reproduction, competition with the more warm-water adapted red king crab, exclusion by warm-water predators, or habitat requirements for settlement of larvae (Armstrong et al 1985, 1987; Somerton, 1985).

## 3. Stock structure

Stock structure of blue king crab in the North Pacific is largely unknown. Samples were collected in 2009-2011 by a graduate student at the University of Alaska to support a genetic study on blue king crab population structure. Aspects of blue king crab harvest and abundance trends, phenotypic characteristics, behavior, movement, and genetics will be evaluated by the author following the guidelines in the AFSC report entitled "Guidelines for determination of spatial management units for exploited populations in Alaskan groundfish fishery management plans" by P. Spencer (unpublished report).

The potential for species interactions between blue king crab and red king crab as a potential reason for PIBKC shifts in abundance and distribution were addressed in a previous assessment (Foy, 2013). Foy (2013) compared the spatial extent of both speices in the Pribilof Islands from 1975 to 2009 and found that, in the early 1980's when red king crab first became abundant, blue king crab males and females dominated the 1 to 7 stations where the species co-occurred in the Pribilof Islands District. Spatially, the stations with co-occurance were all dominated by blue king crab and broadly distributed around the Pribilof Islands. In the 1990's, the red king crab population biomass increased substantially as the blue king crab population biomass decreased. During this time period, the number of stations with co-occurance remained around a maximum of 8, but they were equally dominated by both blue king crab and red king crab-suggesting a direct overlap in distribution at the scale of a survey station. During this time period, the stations dominated
by red king crab were dispersed around the Pribilof Islands. Between 2001 and 2009 the blue king crab population decreased dramatically while the red king crab fluctuated. The number of stations dominated by blue king crab in 2001-2009 was similar to that for stations dominated by red king crab for both males and females, suggesting continued competition for similar habitat. The only stations dominated by blue king crab in the latter period are to the north and east of St. Paul Island. Although blue king crab protection measures also afford protection for the red king crab in this region, red king crab stocks continue to fluctuate (more so than simply accounted for by the uncertainty in the survey).

During the years when the fishery was active (1973-1989, 1995-1999), the Pribilof Islands blue king crab (PIBKC) were managed under the Bering Sea king crab Registration Area Q Pribilof District. The southern boundary of this district is formed by a line from $5436^{\prime} \mathrm{N}$ lat., 168 W long., to 54 36 ' N lat., 171 W long., to 5530 ' N lat., 171 W. long., to 5530 ' N lat., 17330 ' E long., while its northern boundary is a line at the latitude of Cape Newenham ( $5839^{\prime} \mathrm{N}$ lat.), its eastern boundary is a line from 5436 ' N lat., 168 W long., to 5839 ' N lat., 168 W long., to Cape Newenham ( 58 $39^{\prime}$ N lat.), and its western boundary is the United States-Russia Maritime Boundary Line of 1991 (ADF\&G 2008) (Figure 2). In the Pribilof District, blue king crab occupy the waters adjacent to and northeast of the Pribilof Islands (Armstrong et al. 1987). For assessment purposes, the Pribilof District as defined in Figure 2, with the addition of a 20 nm mile strip to the east of the District (bounded by the dotted red line in Figure 2), is considered to define the stock boundary for PIBKC.

## 4. Life History

Blue king crab are similar in size and appearance, except for color, to the more widespread red king crab, but are typically biennial spawners with lesser fecundity and somewhat larger sized (ca. 1.2 mm ) eggs (Somerton and Macintosh 1983; 1985; Jensen et al. 1985; Jensen and Armstrong 1989; Selin and Fedotov 1996). Blue king crab fecundity increases with size, from approximately 100,000 embryos for a $100-110 \mathrm{~mm}$ CL female to approximately 200,000 for a female $>140-\mathrm{mm}$ CL (Somerton and MacIntosh 1985). Blue king crab have a biennial ovarian cycle with embryos developing over a 12 or 13 -month period depending on whether or not the female is primiparous or multiparous, respectively (Stevens 2006a). Armstrong et al. (1985, 1987), however, estimated the embryonic period for Pribilof blue king crab at 11-12 months, regardless of previous reproductive history. Somerton and MacIntosh (1985) placed development at 14-15 months. It may not be possible for large female blue king crabs to support the energy requirements for annual ovary development, growth, and egg extrusion due to limitations imposed by their habitat, such as poor quality or low abundance of food or reduced feeding activity due to cold water (Armstrong et al. 1987; Jensen and Armstrong 1989). Both the large size reached by Pribilof Islands blue king crab and the generally high productivity of the Pribilof area, however, argue against such environmental constraints. Development of the fertilized embryos occurs in the egg cases attached to the pleopods beneath the abdomen of the female crab and hatching occurs February through April (Stevens 2006b). After larvae are released, large female Pribilof blue king crab will molt, mate, and extrude their clutches the following year in late March through mid April (Armstrong et al. 1987).

Female crabs require an average of 29 days to release larvae, and release an average of 110,033 larvae (Stevens 2006b). Larvae are pelagic and pass through four zoeal larval stages which last about 10 days each, with length of time being dependent on temperature: the colder the temperature the slower the development and vice versa (Stevens et al. 2008). Stage I zoeae must find food within 60 hours as starvation reduces their ability to capture prey (Paul and Paul 1980) and successfully
molt. Zoeae consume phytoplankton, the diatom Thalassiosira spp. in particular, and zooplankton. The fifth larval stage is the non-feeding (Stevens et al. 2008) and transitional glaucothoe stage in which the larvae take on the shape of a small crab but retain the ability to swim by using their extended abdomen as a tail. This is the stage at which the larvae searches for appropriate settling substrate and, upon finding it, molts to the first juvenile stage and henceforth remains benthic. The larval stage is estimated to last for 2.5 to 4 months and larvae metamorphose and settle during July through early September (Armstrong et al. 1987; Stevens et al. 2008).

Blue king crab molt frequently as juveniles, growing a few mm in size with each molt. Unlike red king crab juveniles, blue king crab juveniles are not known to form pods. Female king crabs typically reach sexual maturity at approximately five years of age while males may reach maturity at six years of age (NPFMC 2003). Female size at $50 \%$ maturity for Pribilof blue king crab is estimated to be $96-\mathrm{mm}$ carapace length (CL) and size at maturity for males, estimated from chela height relative to CL, is estimated to be $108-\mathrm{mm}$ CL (Somerton and MacIntosh 1983). Skip molting occurs with increasing probability for those males larger than 100 mm CL (NMFS 2005).

Longevity is unknown for this species due to the absence of hard parts retained through molts with which to age crabs. Estimates of 20 to 30 years in age have been suggested (Blau 1997). Natural mortality for male Pribilof blue king crabs has been estimated at $0.34-0.94$ with a mean of 0.79 (Otto and Cummiskey 1990) and a range of 0.16 to 0.35 for Pribilof and St. Matthew Island stocks combined (Zheng et al. 1997). An annual natural mortality of $0.2 \mathrm{yr}^{-1}$ for all king crab species was adopted in the federal crab fishery management plan for the BSAI areas (Siddeek et al. 2002). A rate of $0.18 \mathrm{yr}^{-1}$ is currently used for PIBKC.

## 5. Management history

The blue king crab fishery in the Pribilof District began in 1973 with a reported catch of 590 t by eight vessels (Table 9; Figure 3). Landings increased during the 1970s and peaked at a harvest of $5,000 \mathrm{t}$ in the $1980 / 81$ season (Table 9; Figure 3), with an associated increase in effort to 110 vessels (ADFG 2008). The fishery occurred September through January, but usually lasted less than 6 weeks (Otto and Cummiskey 1990; ADFG 2008). The fishery was male only, and legal size was $>16.5 \mathrm{~cm}$ carapace width (NPFMC 1994). Guideline harvest levels (GHL) were 10 percent of the abundance of mature males or 20 percent of the number of legal males (ADFG 2006).

PIBKC have occurred as bycatch in the eastern Bering Sea snow crab (Chionoecetes opilio) fishery, the western Bering Sea Tanner crab (Chionoecetes bairdi) fishery, the Bering Sea hair crab (Erimacrus isenbeckii) fishery, and the Pribilof red and blue king crab fisheries (Tables 10 and 11). In addition, blue king crab have been taken as bycatch in groundfish fisheries by both fixed and trawl gear, primarily those targeting Pacific cod, flathead sole and yellowfin sole (Tables 10-12).

Amendment 21a to the BSAI Groundfish FMP prohibits the use of trawl gear in the Pribilof Islands Habitat Conservation Area (subsequently renamed the Pribilof Islands Habitat Conservation Zone in Amendment 43; Figure 4), which the amendment also established (NPFMC 1994). The amendment went into effect January 20, 1995 and protects the majority of crab habitat in the Pribilof Islands area from the impact from trawl gear.

Declines in the PIBKC stock after 1995 resulted in a closure of directed fishing from 1999 to the present. The stock was declared overfished in September 2002, and ADFG developed a rebuilding harvest strategy as part of the NPFMC comprehensive rebuilding plan for the stock. The rebuilding
plan also included the closure of the stock to directed fishing until it was rebuilt. In 2009, NMFS determined that the PIBKC stock was not rebuilding in a timely manner and would not meet the rebuilding horizon of 2014. Subsequently, Amendment 43 to the King and Tanner Crab Fishery Management Plan (FMP) and Amendment 103 to the BSAI Groundfish FMP to rebuild the PIBKC stock were adopted by the Council in 2012 and approved by the Secretary of Commerce in early 2015. Amendment 103 closes the Pribilof Islands Habitat Conservation Zone (Figure 4) to pot fishing for Pacific cod to promote bycatch reduction on PIBKC. Amendment 43 amends the prior rebuilding plan to incorporate new information on the likely rebuilding timeframe for the stock, taking into account environmental conditions and the status and population biology of the stock (NPFMC 2014a).

## D. Data

## 1. Summary of new information

The time series of retained and discarded catch in the crab fisheries was updated for 2016/17 from ADFG data (no retained catch, no bycatch mortality; Tables 10 and 11). The time series of discards in the groundfish pot and trawl fisheries (Tables 10 and 11) were updated for 2009/10-2016/17 using NMFS Alaska Regional Office (AKRO) estimates obtained from the AKFIN database (as updated on Aug. 30, 2017). Results from the 2017 NMFS EBS bottom trawl survey were added to the assessment (Tables 15 and 16), based on the "new" standardization described in the 2015 assessment (Stockhausen, 2015).

## 2. Fishery data

## 2.a. Retained catch

Retained pot fishery catches (live and deadloss landings data) are provided for 1973/74 to 2015/16 (Table 9, Figure 3), including the 1973/74 to 1987/88 and 1995/96 to 1998/99 seasons when blue king crab were targeted in the Pribilof Islands District. In the 1995/96 to 1998/99 seasons, blue king crab and red king crab were fished under the same Guideline Harvest Level (GHL). Total allowable catch (TAC) for a directed fishery has been set at zero since 1999/2000; there was no retained catch in the 2016/17 crab fishing season.

## 2.b. Bycatch and discards:

## Crab pot fisheries

Non-retained (directed and non-directed) pot fishery catches are provided for sublegal males (<138 mm CL), legal males ( $\geq 138 \mathrm{~mm}$ CL), and females based on data collected by onboard observers in the crab fisheries (Table 10). Catch weight was calculated by first determining the mean weight (in grams) for crabs in each of three categories: legal non-retained, sublegal, and female. The average weight for each category was then calculated from length frequency tables, where the carapace length ( $z$; in mm ) was converted to weight ( $w$; in g ) using the following equation:

$$
\begin{equation*}
w=\alpha \cdot z^{\beta} \tag{1}
\end{equation*}
$$

Values for the length-to-weight conversion parameters $\alpha$ and $\beta$ were applied across the time period: males) $\alpha=0.000508, \beta=3.106409$; females) $\alpha=0.02065, \beta=2.27$ (Daly et al. 2014). Average weights $(\bar{W})$ for each category were calculated using the following equation:

$$
\begin{equation*}
\bar{W}=\frac{\sum w_{z} \cdot n_{z}}{\sum n_{z}} \tag{2}
\end{equation*}
$$

where $w_{z}$ is crab weight-at-size $z$ (i.e., carapace length) using Equation 1 , and $n_{z}$ is the number of crabs observed at that size in the category. Finally, estimated total non-retained weights for each crab fishery were the product of average weight $(\bar{W})$, CPUE based on observer data, and total effort (pot lifts) in each fishery.

Historical non-retained catch data are available from 1996/97 to present from the snow crab general, snow crab CDQ, and Tanner crab fisheries (Table 10, Bowers et al. 2011), although data may be incomplete for some of these fisheries. Prior to $1998 / 99$, limited observer data exists (for catcher-processor vessels only), so non-retained catch before this date is not included here. For this assessment, a $20 \%$ handling mortality rate was applied to the bycatch estimates to calculate non-retained crab mortality in these pot fisheries (Table 11). In previous assessments, a handling mortality rate of $50 \%$ was applied to bycatch in the pot fisheries. The revised value used here is now consistent with the rates used in other king crab assessments (e.g., Zheng et al., 2016).

No bycatch mortality occurred in the crab fisheries in 2016/17. In 2015/16, though, several PIBKC were incidentally caught in the crab fisheries, yielding an expanded estimate of 0.067 t bycatch mortality (using a handling mortality rate of $20 \%$; Table 10). Bycatch mortality during 2015/16 was the first non-zero bycatch mortality in the crab fisheries since 2010/11.

## Groundfish fisheries

The AKRO estimates of non-retained catch from all groundfish fisheries in 2016/17, as available through the AKFIN database (accessed Aug. 30, 2017), are included in this report (Tables 10-12). Updated estimates for $2009 / 10-2016 / 17$ were obtained through the AKFIN database.

Groundfish bycatch data from before 1999 are available only in INPFC reports and are not included in this assessment. Non-retained crab catch data in the groundfish fisheries are available from 1991/92 to present. Between 1991 and December 2001, bycatch was estimated using the "blend method." From January 2003 to December 2007, bycatch was estimated using the Catch Accounting System (CAS), based on substantially different methods than the "blend." Starting in January 2008, the groundfish observer program changed the method in which they speciate crab to better reflect their hierarchal sampling method and to account for broken crab that in the past were only identified to genus. In addition, the haul-level weights collected by observers were used to estimate the crab weights through CAS instead of applying an annual (global) weight factor to convert numbers to biomass. Spatial resolution was at the NMFS statistical area. Beginning in January 2009, ADFG statistical areas ( 1 ^o $\$$ longitude $\times 0.5^{\circ}$ latitude) were included in groundfish production reports and allowed an increase in the spatial resolution of bycatch estimates from the NMFS statistical areas to the state statistical areas. Bycatch estimates (2009-present) based on the state statistical areas were first provided in the 2013 assessment, and improved methods for aggregating observer data were used in the 2014 and 2015 assessments (see Stockhausen, 2015). The estimates obtained this
year are based on the same methods as those used in the 2014-2016 assessments. Detailed results from this process are presented in Appendix A.

To assess crab mortalities in the groundfish fisheries, an $80 \%$ handling mortality rate was applied to estimates of bycatch in trawl fisheries, and a $20 \%$ handling mortality rate was applied to fixed gear fisheries using pot and hook and line gear (Tables 10-11). As noted above, previous assessments used a handling mortality rate of $50 \%$ for bycatch mortality in the fixed gear fisheries.

In 2016/17, fisheries targeting rock sole (Lepidopsetta spp.) accounted for $68 \%$ of the bycatch of PIBKC in the groundfish fisheries, with fisheries targeting yellowfin sole (Limanda aspera) and Pacific cod (Gadus microcephalus) accounting for $16 \%$ each. In contrast, fisheries targeting Pacific cod accounted for $48 \%$ of the estimated total PIBKC bycatch (by weight) in the groundfish fisheries in 2015/16, with fisheries targeting yellowfin sole accounting for another 43\% (Table 12). In 2013/14 and 2014/15, bycatch of PIBKC occurred almost exclusively in the Pacific cod fisheries (99.4\% by weight, Table 4). The flathead sole (Hippoglossoides elasodon) fishery has also accounted for a substantial fraction of the bycatch at times.

Since the 2009/10 crab fishing season, Pribilof Islands blue king crab have been taken as bycatch in the groundfish fisheries only by hook and line and non-pelagic trawl gear (Table 13). Starting in 2015, as a consequence of Amendment 43 to the BSAI Groundfish FMP, the Pribilof Islands Habitat Conservation Area was formally closed to pot fishing for Pacific cod in order to promote recovery of the PIBKC stock. In 2016/17, non-pelagic trawl gear accounted for $83 \%$ (by weight) of PIBKC bycatch in the groundfish fisheries. In 2015/16, by contrast, non-pelagic trawl gear accounted for only $52 \%$ the bycatch. In 2013/14 and 2014/15, hook and line gear accounted for the total bycatch of PIBKC, while in $2012 / 13$, it accounted for only $20 \%$ of the bycatch (by weight)-whereas non-pelagic trawl gear accounted for $80 \%$. Although these appear to be large interannual changes, the actual bycatch amounts involved are fairly small and interannual variability is consequently expected to be rather high.

## 2.c. Catch-at-length

Not applicable.

## 3. Survey data

The 2017 NMFS EBS bottom trawl survey was conducted between May and August of this year. Survey results for PIBKC are based on the stock area first defined in the 2013 assessment (Foy, 2013), which includes the Pribilof District and a 20 nm strip adjacent to the eastern edge of the District (Figure 2). The adjacent area was defined as a result of the new rebuilding plan and the concern that crab outside the Pribilof District were not being accounted for in the assessment.

In 2017, the survey caught 23 blue king crab in 86 stations across the stock area, while 20 , 28 , and 33 crab were caught across the same stations in the 2014-2016 surveys, respectively (Table ??). Four immature males were caught in 2017, similar to numbers caught in 2014-2016 (5, 4 and 5, respectively). Four mature males (three of which was legal size) were caught in 2017, compared with 5,13 and 3 in 2014-2016, respectively. Seven immature females were caught in 2017; only one was caught in 2014 and none in 2015, but five in 2016. Finally, eight mature females were caught in 2017, compared with only 4 in 2014, 11 in 2015, and 19 in 2016.

The area-swept estimate of mature male abundance in the stock area at the time of the survey was $91,000( \pm 89,000)$, representing an increase from $56,000( \pm 62,000)$ in 2016 (Table 15). The abundance estimate for immature males in 2017 was $68,000( \pm 103,000)$, while it was $94,000( \pm 95,000)$ in 2016. The area-swept estimate for immature female abundance in 2017 was $188,000( \pm 275,000)$, larger than in $2016(132,000 \pm 130,000)$, while that for mature females was only $162,000( \pm 169,000)$, smaller than that in $2016(323,000 \pm 328,000)$. None of the changes were statistically significant.

The area-swept estimate of mature male biomass in the stock area at the time of the 2017 survey was $253 \mathrm{t}( \pm 254 \mathrm{t})$, while it was $129 \mathrm{t}( \pm 154 \mathrm{t})$ in 2016 (Table 16). The biomass estimate for immature males in 2017 was 45 t ( $\pm 68 \mathrm{t}$ ), compared with $70 \mathrm{t}( \pm 67 \mathrm{t})$ in 2016 . The area-swept estimate for immature female biomass in 2017 was 107 t ( $\pm 170 \mathrm{t}$ ); in 2016, it was $49 \mathrm{t}( \pm 48 \mathrm{t})$. For mature females, the estimated swept-area biomass was $152 \mathrm{t}( \pm 166 \mathrm{t})$; in 2016 , it was $352 \mathrm{t}( \pm 340 \mathrm{t})$.

One feature that characterizes survey-based estimates of abundance and biomass for PIBKC is the large uncertainty (cv's on the order of $0.5-1$ ) associated with the estimates, which complicates the interpretation of sometimes large interannual swings in estimates (Tables 15 and 16, Figures 5-8). Estimated total abundance of male PIBKC from the NMFS EBS bottom trawl survey declined from $\sim 24$ million crab in 1975, the first year of the "standardized" survey, to $\sim 150,000$ in 2016 (the lowest estimated abundance since 2004, which was the minimum for the time series; Table 15, Figures 5 and 6). Following a general decline to a low-point in 1985 ( $\sim 500,000$ males), abundance increased by a factor of 10 in the early1990s, then generally declined (with small amplitude oscillations superimposed) to the present. Estimated female abundance generally followed a similar trend. It spiked at 180 million crab in 1980, from $\sim 13$ million crab in 1975 and only $\sim 1$ million in 1979, then returned to more typical levels in 1981 ( $\sim 6$ million crab). More recently, abundance has fluctuated around 200,000 females. Estimated biomass for both males and females have followed similar trends similar to those in abundance (Table 16, Figures 7 and 8).

Size frequencies for males by shell condition from recent surveys (2012-2017) are illustrated in Figure 9. Size frequencies for all males across the time series are shown in Figure 10. While Figure 10 suggested a recent trend toward larger sizes in 2014-15, this does not appear to have continued in 2016. These plots provide little evidence of recent recruitment.

Size frequencies for females by shell condition are presented in Figure 11 from recent surveys (2012-2017). Size frequencies for all females are shown in 12. These also provide little indication of recent recruitment.

The small numbers of crab caught in recent surveys make it difficult to draw firm conclusions regarding spatial patterns (see figures in Appendix B). That said, the spatial pattern of PIBKC abundance in recent surveys is generally centered fairly compactly within the Pribilof District to the east of St. Paul Island (although 2015 is an exception) and north of St. George Island, within a 60 nm radius of St . Paul.

## E. Analytic Approach

## 1. History of modeling approaches

A catch survey analysis has been used for assessing the stock in the past, although it is not currently in use. In October 2013, the SSC concurred with the CPT that the PIBKC stock falls under Tier 4
for status determination but it recommended that the OFL be calculated using a Tier 5 approach, with ABC based on a $10 \%$ buffer. Subsequently, a $25 \%$ buffer has been used to calculate ABC.

In the 2013 and 2014 assessments (Foy 2013; Stockhausen 2014), "current" MMB-at-mating was projected from the time of the latest survey using an inverse-variance averaging approach to smoothing annual survey biomass estimates because the uncertainties associated with the annual estimates are extremely large. In the 2015 assessment (Stockhausen, 2015), an alternative approach to smoothing based on a Random Effects model was presented and subsequently adopted by the CPT and SSC to use in estimating $B_{M S Y}$ and "current" MMB-at-mating. The Random Effects model (Appendix C) is used in this assessment.

## 2. Model Description

See Appendix C.

## 3. Model Selection and Evaluation

Not applicable

## 4. Results

See Appendix C.

## F. Calculation of the OFL

## 1. Tier Level:

Based on available data, the author recommended classification for this stock is Tier 4 for stock status level determination defined by Amendment 24 to the Fishery Management Plan for the Bering Sea/Aleutian Islands King and Tanner Crabs (NPFMC 2008a).

In Tier 4, stock status is based on the ratio of "current" spawning stock biomass ( $B$ ) to $B_{M S Y}$ (or a proxy thereof, $B_{M S Y_{\text {proxy }}}$, also referred to as $B_{R E F}$ ). MSY (maximum sustained yield) is the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions. The fishing mortality that, if applied over the long-term, would result in MSY is $F_{M S Y} . B_{M S Y}$ is the long-term average stock size when fished at FMSY, and is based on mature male biomass at the time of mating ( $M M B_{\text {mating }}$ ), which serves as an approximation for egg production. $M M B_{\text {mating }}$ is used as a basis for $B_{M S Y}$ because of the complicated female crab life history, unknown sex ratios, and male only fishery. Although $B_{M S Y}$ cannot be calculated for a Tier 4 stock, a proxy value ( $B_{M S Y_{p r o x y}}$ or $B_{R E F}$ ) is defined as the average biomass over a specified time period that satisfies the conditions under which $B_{M S Y}$ would occur (i.e., equilibrium biomass yielding MSY under an applied $F_{M S Y}$ ).

The time period for establishing $B_{M S Y_{\text {proxy }}}$ is assumed to be representative of the stock being fished at an average rate near FMSY and fluctuating around $B_{M S Y}$. The SSC has endorsed using the time periods 1980-84 and 1990-97 to calculate $B_{M S Y_{\text {proxy }}}$ for Pribilof Islands blue king crab to avoid
time periods of low abundance possibly caused by high fishing pressure. Alternative time periods (e.g., 1975 to 1979) have also been considered but rejected (Foy 2013). Considerations for choosing the current time periods included:

## A. Production potential

1) Between 2006 and 2013 the stock does appear to be below a threshold for responding to increased production based on the lack of response of the adult stock biomass to slight fluctuations in recruitment (male crab 120-134 mm) (Figure 20 in Foy 2013).
2) An estimate of surplus production $\left(A S P_{t}=M M B_{t+1}{ }^{\smile} M M B_{t}+\right.$ totalcatch $\left._{t}\right)$ suggested that only meaningful surplus existed only in the late 1970s and early 1980s while minor surplus production in the early 1990s may have led to the increases in biomass observed in the late 1990s.
3) Although a climate regime shift where temperature and current structure changes are likely to impact blue king crab larval dispersal and subsequent juvenile crab distribution, no apparent trends in production before or after 1978 were observed (Foy 2013). There are few empirical data to identify trends that may allude to a production shift. However, further analysis is warranted given the paucity of surplus production and recruitment subsequent to 1981 and the spikes in recruits (male crab 120-134 mm) /spawner (MMB) observed in the early 1990s and 2009 (Figure 21 in Foy 2013).

## B. Exploitation rates

Exploitation rates fluctuated during the open fishery periods from 1975 to 1987 and 1995 to 1998 (Figure 20 in Foy 2013) while total catch increased until 1980, before the fishery was closed in 1987, and increased again in 1995 before closing again in 1999 (Figure 22 in Foy 2013). The current $F_{M S Y_{\text {proxy }}}=M$ is 0.18 , so time periods with greater exploitation rates should not be considered to represent a period with an average rate of fishery removals.

## C. Recruitment

Subsequent to increases in exploitation rates in the late 1980s and 1990s, the quantity $\ln$ (recruits/MMB) dropped, suggesting that exploitation rates at the levels of $F_{M S Y_{p r o x y}}=M$ were not sustainable.

Thus, $M M B_{\text {mating }}$ is the basis for calculating $B_{M S Y_{\text {proxy }}}$. The formulas used to calculate $M M B_{\text {mating }}$ from MMB at the time of the survey $\left(M M B_{\text {survey }}\right)$ are documented in Appendix C. For this stock, $B_{M S Y_{\text {proxy }}}$ was calculated using the random effects model-smoothed estimates for $M M B_{\text {survey }}$ from the survey time series (Table 17) in the formula for $M M B_{\text {mating }} . B_{M S Y_{\text {proxy }}}$ is the average of $M M B_{\text {mating }}$ for the years 1980/81-1984/85 and 1990/91-1997/98 (Table 18) and was calculated as 4,108 t.

In this assessment, "current $\mathrm{B} "(B)$ is the $M M B_{\text {mating }}$ projected for 2017/18. Details of this calculation are also provided in Appendix C. For 2017/18, $B=230 \mathrm{t}$.

Overfishing is defined as any amount of fishing in excess of a maximum allowable rate, $F_{O F L}$, which would result in a total catch greater than the OFL. For Tier 4 stocks, a minimum stock size threshold (MSST) is specified as $0.5 \cdot B_{M S Y_{p r o x y}}$. If $B$ drops below the MSST, the stock is considered to be overfished.

## 2. Parameters and stock sizes

- $B_{M S Y_{\text {proxy }}}\left(B_{R E F}\right)=4,108 \mathrm{t} \cdot M=0.18 \mathrm{yr}^{\wedge}\{-1\} \cdot B=230 \mathrm{t}$

## 3. OFL specification

## 3.a. Stock status level

In the Tier 4 OFL-setting approach, the "total catch OFL" and the "retained catch OFL" are calculated by applying the $F_{O F L}$ to all crab at the time of the fishery (total catch OFL) or to the mean retained catch determined for a specified period of time (retained catch OFL).
The Tier $4 F_{O F L}$ is derived using the $F_{O F L}$ Control Rule (Figure 13), where the Stock Status Level (level a, b or c; equations 3-5) is based on the relationship of $B$ to $B_{M S Y_{p r o x y}}$.
Stock Status Level $F_{O F L}$

$$
\begin{gather*}
a . \quad B / B_{M S Y_{\text {proxy }}}>1.0 \quad F_{O F L}=\gamma \cdot M  \tag{3}\\
b . \quad \beta<B / B_{M S Y_{\text {proxy }}} \leq 1.0 \quad F_{O F L}=\gamma \cdot M\left[\left(B / B_{M S Y_{\text {proxy }}}-\alpha\right) /(1-\alpha)\right]  \tag{4}\\
c . \quad B / B_{M S Y_{\text {proxy }}} \leq \beta \quad F_{\text {directed }}=0, \quad F_{O F L} \leq F_{M S Y} \tag{5}
\end{gather*}
$$

When $\mathrm{B} / B_{M S Y_{p r o x y}}$ is greater than 1 (Stock Status Level a), $F_{O F L_{p r o x y}}$ is given by the product of a scalar ( $\gamma=1.0$, nominally) and $M$. When $B / B_{M S Y_{p r o x y}}$ is less than 1 and greater than the critical threshold $\beta(=0.25)$ (Stock Status Level b), the scalar $\alpha(=0.1)$ determines the slope of the non-constant portion of the control rule for $F_{O F L_{\text {proxy }} \text {. Directed fishing mortality is set to zero }}$ when the ratio $B / B_{M S Y_{\text {proxy }}}$ drops below $\beta$ (Stock Status Level c). Values for $\alpha$ and $\beta$ are based on a sensitivity analysis of the effects on $B / B_{M S Y_{p r o x y}}$ (NPFMC 2008a).

## 3.b. Basis for MMB-at-mating

The basis for projecting MMB from the survey to the time of mating is discussed in detail in Appendix C.

## 3.c. Specification of $F_{O F L}$, OFL and other applicable measures

Table 5: Basis for the OFL (Table 3 repeated). All units in metric tons.

| Year | Tier | $\boldsymbol{B}_{\text {MSY }}$ | $\begin{array}{r} \text { Current } \\ \text { MMB }_{\text {mating }} \end{array}$ | $\begin{gathered} B / B_{\text {MSY }} \\ \left(\mathrm{MMB}_{\text {mating }}\right) \end{gathered}$ | $\gamma$ | $\begin{gathered} \hline \text { Years to define } \\ B_{\mathrm{MSY}} \\ \hline \end{gathered}$ | Natural <br> Mortality | P* |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 6: Basis for the OFL (Table 4 repeated). All units in millions lbs.

## 4. Specification of the retained catch portion of the total catch OFL

The retained portion of the catch for this stock is zero ( 0 t ).

## 5. Recommendations:

For $2017 / 18, B_{M S Y_{\text {proxy }}}=4,108 \mathrm{t}$, derived as the mean $M M B_{\text {mating }}$ from 1980/81 to $1984 / 85$ and $1990 / 91$ to $1997 / 98$ using the random effects model-smoothed survey time series. The stock demonstrated highly variable levels of MMB during both of these periods, likely leading to uncertain approximations for $B_{M S Y}$. Crabs were highly concentrated during the EBS bottom trawl surveys and male biomass estimates were characterized by poor precision due to limited numbers of tows with crab catches.
$M M B_{\text {mating }}$ for $2017 / 18$ was estimated at 230 t . The $B / B_{M S Y_{p r o x y}}$ ratio corresponding to the biomass reference is $0.06 . B / B_{M S Y_{\text {proxy }}}$ is $<\beta$, therefore the stock status level is c, $F_{\text {directed }}=0$, and $F_{O F L} \leq F_{M S Y}$ (as determined in the Pribilof Islands District blue king crab rebuilding plan). Total catch OFL calculations were explored in 2008 to adequately reflect the conservation needs
with this stock and to acknowledge the existing non-directed catch mortality (NPFMC 2008a). The preferred method was a total catch OFL equivalent to the average catch mortalities between $1999 / 2000$ and 2005/06. This period was after the targeted fishery was closed and did not include recent changes to the groundfish fishery that led to increased blue king crab bycatch. The OFL for $2017 / 18$, based on an average catch mortality, is 1.16 t .

## G. Calculation of the ABC

To calculate an Annual Catch Limit (ACL) to account for scientific uncertainty in the OFL, an acceptable biological catch (ABC) control rule was developed such that ACL=ABC. For Tier 3 and 4 stocks, the ABC is set below the OFL by a proportion based a predetermined probability that the ABC would exceed the OFL $\left(\mathrm{P}^{*}\right)$. Currently, $\mathrm{P}^{*}$ is set at 0.49 and represents a proportion of the OFL distribution that accounts for within assessment uncertainty ( $\sigma_{w}$ ) in the OFL to establish the maximum permissible $\mathrm{ABC}\left(\mathrm{ABC}_{\text {max }}\right)$. Any additional uncertainty to account for uncertainty outside of the assessment methods $\left(\sigma_{b}\right)$ is considered as a recommended ABC below $\mathrm{ABC}_{\text {max }}$. Additional uncertainty is included in the application of the ABC by adding the uncertainty components as $\sigma_{\text {total }}=\sqrt{\sigma_{w}^{2}+\sigma_{b}^{2}}$. For the PIBKC stock, the CPT has recommended, and the SSC has approved, a constant buffer of $25 \%$ to the OFL (NPFMC, 2014b).

## 1. Specification of the probability distribution of the OFL used in the ABC

The OFL was set based on a Tier 5 calculation of average catch mortalities between 1999/2000 and 2005/06 to adequately reflect the conservation needs with this stock and to acknowledge the existing non-directed catch mortality. As such, the OFL does not have an associated probability distribution.

## 2. List of variables related to scientific uncertainty considered in the OFL probability distribution

None. The OFL is based on a Tier 5 calculation and does not have an associated probability distribution. However, compared to other BSAI crab stocks, the uncertainty associated with the estimates of stock size and OFL for Pribilof Islands blue king crab is very high due to insufficient data and the small spatial extent of the stock relative to the survey sampling density. The coefficient of variation for the estimate of mature male biomass from the surveys for the most recent year is 0.51 , and has ranged between 0.17 and 1.00 since the 1980 peak in biomass.

## 3. List of additional uncertainties considered for alternative $\sigma_{b}$ applications to the ABC

Several sources of uncertainty are not included in the measures of uncertainty reported as part of the stock assessment:

- Survey catchability and natural mortality uncertainties are not estimated but rather are prespecified.
- $F_{M S Y}$ is assumed to be equal to $\gamma \cdot M$ when applying the OFL control rule, where the proportionality constant $\gamma$ is assumed to be equal to 1 and $M$ is assumed to be known.
- The coefficients of variation for the survey estimates of abundance for this stock are very high.
- $B_{M S Y}$ is assumed to be equivalent to average mature male biomass. However, stock biomass has fluctuated greatly and targeted fisheries only occurred from 1973-1987 and 1995-1998 so considerable uncertainty exists with this estimate of $B_{M S Y}$.

## 4. Recommendations:

For 2017/18, $F_{\text {directed }}=0$ and the total catch OFL is based on catch biomass would maintain the conservation needs with this stock and acknowledge the existing non-directed catch mortality. In this case, the $A B C$ based on a $25 \%$ buffer of the average catch between 1999/2000 and 2005/2006 would be 0.87 t .

Table 7: Management performance (Table). All units in metric tons. The OFL is a total catch OFL for each year.

| Year | MSST | Biomass <br> $\left(\mathbf{M M B}_{\text {mating }}\right.$ | TAC | Retained <br> Catch | Total Catch <br> Mortality | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2013 / 14$ | $2,001 \mathrm{~A}$ | 225 A | closed | 0 | 0.03 | 1.16 | 1.04 |
| $2014 / 15$ | $2,055 \mathrm{~A}$ | 344 A | closed | 0 | 0.07 | 1.16 | 0.87 |
| $2015 / 16$ | $2,058 \mathrm{~A}$ | 361 A | closed | 0 | 1.18 | 1.16 | 0.87 |

## H. Rebuilding Analyses

Rebuilding analyses results summary: A revised rebuilding plan analysis was submitted to the U.S. Secretary of Commerce in 2014 because NMFS determined that the stock was not rebuilding in a timely manner and would not meet the rebuilding horizon of 2014 . The Secretary approved the plan
in 2015, as well as the two amendments that implement it (Amendment 43 to the King and Tanner Crab Fishery Management Plan and Amendment 103 to the BSAI Groundfish Fishery Management Plan). These amendments impose a closure to all fishing for Pacific cod with pot gear in the Pribilof Islands Habitat Conservation Zone. This measure was designed to protect the main concentration of the stock from the fishery with the highest observed rates of bycatch (NPFMC, 2014a). The area has been closed to trawling since 1995.

## I. Data Gaps and Research Priorities

Given the large CVs associated with the survey abundance and biomass estimates for the Pribilof Islands blue king crab stock, assessment of this species might benefit from additional surveys using alternative gear at finer spatial resolution. Jared Weems, a PhD student at University of Alaska, Fairbanks, is conducting research on alternative survey designs, including visual censuses, drop camera, and collector traps to better quantify PIBKC in a study funded by NPRB. Other data gaps include stock-specific natural mortality rates and a lack of understanding regarding processes apparently preventing successful recruitment to the Pribilof District.

## Introduction

Bycatch of PIBKC in the groundfish fisheries during 2009/10-2016/17 was downloaded from AKFIN on Aug. 30, 2017 as file ("FromAKFIN.PIBKC.BycatchEstimates.2009-2016.csv").

## Bycatch by gear type

The bycatch of PIBKC by gear type (trawl or fixed) are presented in the following table. Catches using pelagic and non-pelagic trawl gear have been aggregated as "trawl" gear, while catches using hook-and-line (longline) and pot gear have been aggregated as "fixed" gear.

Table 1: Bycatch of PIBKC in the groundfish fisheries, by gear type. Biomass is in kilograms.

Figure 1: Bycatch of PIBKC in the groundfish fisheries by gear type.

## Bycatch by target type

Bycatch of PIBKC in the groundfish fisheries is presented by groundfish target type in this section. Groundfish targets with less than 10 kg bycatch over the 2009-2016 period have been dropped from the table and figure.

Table 2: Bycatch of PIBKC in the groundfish fisheries by target type. Biomass is in kilograms.

## Introduction

This report presents results from time series of aggregate abundance, biomass and size compositions from the annual NMFS EBS bottom trawl survey for Pribilof Islands blue king crab (PIBKC), i.e. blue king crab in the Pribilof District of the eastern Bering Sea (Figure 1), based on haul data and survey strata files downloaded from AKFIN on Aug. 30, 2017.

Figure 1: Map of the Pribilof District, which defines the stock area for the Pribilof Islands blue king crab stock. The grid indicates the locations of NMFS EBS survey stations.

Aggregate (abundance, biomass) time series were calculated for different components of the PIBKC stock, including immature and mature females and immature, mature, sublegal, and legal male crab based of the following size-based criteria:

Table 1: Size groupings for various components of the PIBKC stock used in this report.

| sex | size.range | category |
| :--- | :--- | :--- |
| female | $<100 \mathrm{~mm} \mathrm{CL}$ | immature female |
| male | $<120 \mathrm{~mm} \mathrm{CL}$ | immature male |
| female | $>99 \mathrm{~mm} \mathrm{CL}$ | mature female |
| male | $>119 \mathrm{~mm} \mathrm{CL}$ | mature male |
| male | $<135 \mathrm{~mm} \mathrm{CL}$ | sublegal male |
| male | $>134 \mathrm{~mm} \mathrm{CL}$ | legal male |
| female | all | all females |
| male | all | all males |

## Annual survey abundance and biomass

Annual survey abundance and biomass for PIBKC were calculated from the survey haul data as if the survey were conducted using a random-stratified sampling design (it uses a fixed grid).

The following plots illustrate time series trends in Tanner crab survey abundance and biomass by sex and area.

Figure 2: NMFS survey abundance time series for female PIBKC. Upper plot is entire time series, lower plot since 2001.

Figure 3: NMFS survey abundance time series for male PIBKC. Upper plot is entire time series, lower plot since 2001.

Figure 4: NMFS survey biomass time series for female PIBKC. Upper plot is entire time series, lower plot since 2001.

Figure 5: NMFS survey biomass time series for male PIBKC. Upper plot is entire time series, lower plot since 2001.

The following two tables document the annual sampling effort (the number of survey hauls, the number of survey hauls with non-zero catch, and the number of crab caught) by the NMFS bottom trawl survey in the Pribilof District by PIBKC population category.

Table 2: Sample sizes (number of survey hauls, number hauls where crab were caught, number of crab caught) for the NMFS EBS trawl survey in the Pribilof District each year, for female population components.

| year | survey number of hauls | immature females |  | mature females |  | all females |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The following two tables document the estimated annual PIBKC abundance and associated uncertainty (as the coefficient of variation) in the NMFS bottom trawl survey by PIBKC populaton category. The estimated abundance and uncertainity for each category is calculated using a sweptarea approach as if the EBS trawl survey were conducted using a stratified-random sampling design, rather than as a grid-based design. While re-calculated from the "raw" survey data using a completely independent approach, the estimates are the same (to 4 or 5 decimal places) as those provided in the annual survey Technical Memoranda.

Table 4: Estimated annual abundance of female PIBKC population components from the NMFS EBS trawl survey.

| year | immature females |  | mature females |  | all females |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Size compositions

Annual size compositions for PIBKC in the NMFS EBS trawl survey were calculated by sex, shell condition, and 5 mm size (carapace width) bin, accumulating individuals $>200 \mathrm{~mm}$ CL in the last size bin (195-200 mm CL). There is no need here to distinguish among the population components used above to present abundance and biomass trends (e.g., immature females) in the following size compositions because those components were based on size ranges that can be extracted from the size compositions.

## By sex

Size compositions for PIBKC from the NMFS EBS trawl survey are presented here by sex for the entire survey time period (1975-present) and for 2001-present.

## By sex and shell condition

Size compositions for PIBKC from the NMFS EBS trawl survey are presented here by sex for the entire survey time period (1975-present) and for 2001-present.

## Introduction

This is an appendix to the 2017 stock assessment chapter for the Pribilof Islands blue king crab stock (PIBKC). It presents results for status determination (is overfishing occurring?, is the stock overfished?) for the current year using the "rPIBKC"" R package developed by the assessment author. The rPIBKC package (source code and R package) is available under version control at https://github.com/wStockhausen/rPIBKC.git.

## Status Determination and OFL calculations

For all crab stocks managed by the NPFMC, overfishing is evaluated by comparing the previous year's catch mortality (retained + discard mortality) to the previous year's OFL: if the former is greater than the latter, then overfishing is occurring. Overfished status is assessed with respect to MSST, the Minimum Stock Size Threshold. If stock biomass drops below the MSST, the stock is considered to be overfished. For crab stocks, MSST is one-half $B_{M S Y}$, where $B_{M S Y}$ is the longterm spawning stock biomass when the stock is fished at maximum sustainable yield (MSY). Thus, the stock is overfished if $B / B_{M S Y}<0.5$, where $B$ is the "current"" spawning stock biomass. In general, the overfishing limit (OFL) for the subsequent year is based on $B / B_{M S Y}$ and an " $F_{O F L}$ " harvest control rule, where $F_{O F L}$ is the fishing mortality rate that yields the OFL. Furthermore, if $B / B_{M S Y}<\beta(=0.25)$, directed fishing on the stock is prohibited. For PIBKC, the OFL is based on average historic catch mortality over a specified time period (a Tier 5 approach) and is consequently fixed at 1.16 t .

PIBKC falls into Tier 4 for status determination. For Tier 4 stocks, it is not possible to determine $B_{M S Y}$ and MSST directly. Instead, average mature male biomass (MMB) at the time of mating
("MMB at mating"") is used as a proxy for $B_{M S Y}$, where the averaging is over some time period assumed to be representative of the stock being fished at an average rate near $F_{M S Y}$ and is thus fluctuating around $B_{M S Y}$. For PIBKC, the NPFMC's Science and Statistical Committee (SSC) has endorsed using the disjoint time periods [1980-84, 1990-97] to calculate $B_{M S Y_{p r o x y}}$ to avoid time periods of low abundance possibly caused by high fishing pressure. Alternative time periods (e.g., 1975 to 1979) have also been considered but rejected. Once $B_{M S Y_{\text {proxy }}}$ has been calculated, overfished status is then determined by the ratio $B / B_{M S Y_{\text {proxy }}}$ : the stock is overfished if the ratio is less than 0.5 , where $B$ is taken as"current" MMB-at-mating.

## MMB-at-mating

MMB-at-mating $\left(M M B_{m}\right)$ is calculated from MMB at the time of the annual NMFS EBS bottom trawl survey $\left(M M B_{s}\right)$ by accounting for natural and fishing mortality from the time of the survey to mating. MMB at the time of the survey in year $y$ is calculated from survey data using:

$$
M M B_{s_{y}}=\sum_{z} w_{z} \cdot P_{z} \cdot n_{z, y}
$$

where $w_{z}$ is male weight at size $z(\mathrm{~mm} \mathrm{CL}), P_{z}$ is the probability of maturity at size $z$, and $n_{z, y}$ is survey-estimated male abundance at size $z$ in year $y$.

For a year $y$ prior to the assessment year, $M M B_{m_{y}}$ is given by

1. $M M B_{f_{y}}=M M B_{s_{y}} \cdot e^{-M \cdot t_{s f}}$
2. $M M B_{m_{y}}=\left[M M B_{f_{y}}-R M_{y}-D M_{y}\right] \cdot e^{-M \cdot t_{f m}}$
where $M M B_{f_{y}}$ is the MMB in year $y$ just prior to the fishery, $M$ is natural mortality, $R M_{y}$ is retained mortality on MMB in the directed fishery in year $y, D M_{y}$ is discard mortality on MMB (not on all crab) in all fisheries in year $y$, $t_{s f}$ is the time between the survey and the fishery, and $t_{f m}$ is the time between the fishery and mating.

For the assessment year, the fishery has not yet occurred so $R M$ and $D M$ are unknown. The amount of fishing mortality presumably depends on the (as yet-to-be-determined) overfishing limit, so an iterative procedure is used to estimate MMB-at-mating for the fishery year. This procedure involves:

1. "guess" a value for $F_{O F L}$, the directed fishing mortality rate that yields OFL $\left(F_{O F L_{\max }}=\gamma \cdot M\right.$ is used)
2. determine the OFL corresponding to fishing at $F_{O F L}$ using the following equations:

- $M M B_{f}=M M B_{s} \cdot e^{-M \cdot t_{s f}}$
- $R M_{O F L}=\left(1-e^{-F_{O F L}}\right) \cdot M M B_{s} \cdot e^{-M \cdot t_{s f}}$
- $D M_{O F L}=\theta \cdot \frac{M M B_{f}}{p_{\text {male }}}$
- $O F L=R M_{O F L}+D M_{O F L}$

3. project MMB-at-mating from the "current" survey MMB and the OFL:

$$
\text { - } M M B_{m}=\left[M M B_{f_{y}}-\left(R M_{O F L}+p_{\text {male }} \cdot D M_{O F L}\right)\right] \cdot e^{-M \cdot t_{f m}}
$$

4. use the harvest control rule to determine the $F_{O F L}$ corresponding to the projected MMB-atmating.
5. update the "guess" in 1. for the result in 4.
6. repeat steps 2-5 until the process has converged, yielding self-consistent values for $F_{O F L}$ and MMB-at-mating.
where $p_{\text {male }}$ is the assumed fraction of discard mortality on males. Note that this procedure determines the OFL for the assessment year as well as the current MMB-at-mating. Also note that, while the retained mortality $R M_{O F L}$ is based on the $F_{O F L}$, the discard mortality $D M_{O F L}$ is assumed to be proportional to the MMB at the time of the fishery, with proportionality constant $\frac{\theta}{p_{\text {male }}}$. The constant $\theta$ is determined by the average ratio of discard mortality on MMB $\left(D M_{M M B}\right)$ to MMB at the time of the fishery $\left(M M B_{f}\right)$ over a recent time interval:

$$
\theta=\frac{1}{N} \sum_{y} \frac{D M_{M M B_{y}}}{M M B_{f_{y}}}
$$

where the sum is over the last N years. In addition, $D M_{M M B}$ is assumed to be proprtional to total discard mortality, with that proportionality given by the percenatge of males in the stock.

## Data

Data from the following files were used in this assessment:

- fishery data: ./Data2017AM.Fisheries.csv
- survey data : ./Data2017AM.Surveys.csv

The following figures illustrate the time series of retained PIBKC in the directed fishery and PIBKC incidentally taken in the crab and groundfish fisheries (i.e., bycatch):

Figure 1: Time series of retained PIBKC catch in the directed fishery.

Figure 2: Time series of retained PIBKC catch in the directed fishery (recent time period).

Figure 3: Time series of PIBKC bycatch in the crab and groundfish fisheries.

Figure 4: Time series of PIBKC bycatch in the crab and groundfish fisheries (recent time period).

The following figures illustrate the time series of PIBKC survey biomass in the NMFS EBS bottom trawl survey:

Figure 5: Time series of NMFS EBS bottom trawl survey biomass for PIBKC. Confidence intervals shown are $80 \%$ CI's, assuming lognormal error distributions.

Figure 6: Time series of NMFS EBS bottom trawl survey biomass for PIBKC (recent time period). Confidence intervals shown are $80 \%$ CI's, assuming lognormal error distributions.

Figure 7: Log10-scale time series for the NMFS EBS bottom trawl survey biomass for PIBKC. Confidence intervals shown are $80 \%$ CI's, assuming lognormal error distributions.

## Survey smoothing

For PIBKC, the variances associated with annual survey estimates of MMB are so large that, prior to estimating $B_{M S Y}$ and "current" MMB-at-mating, the survey MMB time series is first smoothed to reduce overall variability. Starting with the 2015 assessment (Stockhausen, 2015), a random
effects (RE) model based on code developed by Jim Ianelli (NOAA/NMFS/AFSC) has been used to perform the smoothing. This is a statistical approach which models annual log-scale changes in "true" survey MMB as a random walk process using

$$
<\ln \left(M M B_{s}\right)>_{y}=<\ln \left(M M B_{s}\right)>_{y-1}+\epsilon_{y}, \text { where } \epsilon_{y} \sim N\left(0, \phi^{2}\right)
$$

as the state equation and

$$
\ln \left(M M B_{s_{y}}\right)=<\ln \left(M M B_{s}\right)>_{y}+\eta_{y}, \text { where } \eta_{y} \sim N\left(0, \sigma_{s_{y}}^{2}\right)
$$

as the observation equation, where $<\ln \left(M M B_{s}\right)>_{y}$ is the estimated "true" log-scale survey MMB in year $y, \epsilon_{y}$ represents normally-distributed process error in year $y$ with standard deviation $\phi, M M B_{s_{y}}$ is the observed survey MMB in year $y, \eta_{y}$ represents normally-distributed $\ln$-scale observation error, and $\sigma_{s_{y}}$ is the log-scale survey MMB standard deviation in year $y$. The $M M B_{s}$ 's and $\sigma_{s}$ 's are observed quantities, the $<\ln \left(M M B_{s}\right)>$ 's and $\phi$ are estimated parameters, and the $\epsilon$ 's are random effects (essentially nuisance parameters) that are integrated out in the solution.

Parameter estimates are obtained by minimizing the objective function

$$
\Lambda=\sum_{y}\left[\ln (2 \pi \phi)+\left(\frac{<\ln \left(M M B_{s}\right)>_{y}-<\ln \left(M M B_{s}\right)>_{y-1}}{\phi}\right)^{2}\right]+\sum_{y}\left(\frac{\ln \left(M M B_{s_{y}}\right)-<\ln \left(M M B_{s}\right)>_{y}}{\sigma_{s_{y}}}\right)^{2}
$$

The model is coded in C ++ and uses AD Model Builder C ++ libraries (Fournier et al., 2012) to minimize the objective function.

## Smoothing results

For comparison, the raw and RE-smoothed survey MMB time series are shown below in Figures $8-10$, on both arithmetic and natural log scales:

Figure 8: Arithmetic-scale raw and smoothed survey MMB time series. Confidence intervals shown are 80\% CIs, assuming lognormal error distributions.

Figure 9: Arithmetic-scale raw and smoothed survey MMB time series, since 2000. Confidence intervals shown are $80 \%$ CIs, assuming lognormal error distributions.

Figure 10: Log-scale raw and smoothed survey MMB time series. Confidence intervals shown are 80\% CIs, assuming lognormalerror distributions.

## Status determination

## Overfishing status

For PIBKC, the total fishing mortality in $2016 / 17$ was 0.3820875 t while the OFL was 1.16 t. Thus, overfishing did not occur in 2016/17.

## Overfished status

As discussed previously, overfished status is determined by the ratio $B / B_{M S Y_{\text {proxy }}}$ : the stock is overfished if the ratio is less than 0.5 , where $B$ is taken as "current" MMB-at-mating. For PIBKC, $B_{M S Y_{\text {proxy }}}$ is obtained by averaging estimated MMB-at-mating over the period [1980/81-1984/85,1990/91-1997/98]. Following recommendations made by the CPT and SSC in 2015 (CPT, 2015; SSC, 2015), $B$ and $B_{M S Y_{\text {proxy }}}$ are based on MMB-at-mating calculated using the RE-smoothed time series of survey biomass projected forward to mating time.

## MMB-at-mating

For comparison, time series for MMB-at-mating using both the raw (unsmoothed) survey MMB time series and the RE-smoothed survey MMB time series were calculated. The results are shown below in Figures 12 and 13:

Figure 11: Estimated time series for MMB at the time of the survey (no smoothing), at the time of the fishery, and at the time of mating.

Figure 12: Estimated time series for MMB using the RE method at the time of the survey (the random effects time series), at the time of the fishery, and at the time of mating.

Values for $B_{M S Y_{\text {proxy }}}$ and the estimated current (2017) MMB at the time of the survey from the raw survey data and the RE-smoothed results are:

Table 1: Estimated $B_{M S Y_{p r o x y}}$ and current MMB at the time of the survey, using the raw survey data and the RE-smoothed data.

| Estimation Type | Current survey MMB $(\mathrm{t})$ | $B_{M S Y_{\text {proxy }}}(\mathrm{t})$ |
| :--- | :---: | :---: |
| raw data | 253 | 5,012 |
| RE-smoothed | 256 | 4,108 |

The value above for $B_{M S Y_{\text {proxy }}}$ using the raw data is shown for illustration only. As noted previously, $B_{M S Y_{\text {proxy }}}$ for this assessment is based on averaging the MMB-at-mating calculated from the RE-smoothed survey MMB (i.e., 4107.8663144 t).

Values for $\theta$, used in the projected MMB calculations, based on averaging over the last three years, are:

Table 2: Estimated values for the heta coefficient.

|  | Estimation Type | $\$ \backslash$ theta $\$$ |
| :---: | :---: | :---: |
| 1 | raw data | 0.0007627 |
| 2 | RE-smoothed | 0.0006203 |

Results from the calculations for $B$ ("current" MMB), overfished status, and an illustrative Tier 4-based OFL for 2017/18 (not used for PIBKC) are:

Table 3: More results from the OFL determination.

|  | quantity | units | raw.data | RE.smoothed |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $B$ ("current" MMB) | t | 227.41 | 230.21 |
| 2 | $B_{M S Y}$ | t | $5,012.14$ | $4,107.87$ |
| 3 | stock status | - | overfished | overfished |
| 4 | $F_{O F L}$ | year $^{-1}$ | 0.00 | 0.00 |
| 5 | $R M_{O F L}$ | t | 0.00 | 0.00 |
| 6 | $D M_{O F L}$ | t | 0.37 | 0.30 |
| 7 | $O F L$ | t | 0.37 | 0.30 |

Because $B / B_{M S Y}$ using RE-smoothed MMB-at-mating from the Table above is 0.056 , the stock is overfished. Furthermore, because $B / B_{M S Y}<\beta(=0.25)$, directed fishing on PIBKC is prohibited.

# Saint Matthew Island Blue King Crab Stock Assessment 2018 

Jie Zheng ${ }^{1}$ and James Ianelli ${ }^{2}$<br>${ }^{1}$ Alaska Department of Fish and Game, jie.zheng@alaska.gov<br>${ }^{2}$ NOAA, jim.ianelli@noaa.gov

September 2018

## Executive Summary

1. Stock: Blue king crab, Paralithodes platypus, Saint Matthew Island (SMBKC), Alaska.
2. Catches: Peak historical harvest was $4,288 \mathrm{t}$ ( 9.454 million pounds) in $1983 / 84^{1}$. The fishery was closed for 10 years after the stock was declared overfished in 1999. Fishing resumed in 2009/10 with a fishery-reported retained catch of 209 t ( 0.461 million pounds), less than half the 529.3 t ( 1.167 million pound) TAC. Following three more years of modest harvests supported by a fishery catch per unit effort (CPUE) of around 10 crab per pot lift, the fishery was again closed in 2013/14 due to declining trawl-survey estimates of abundance and concerns about the health of the stock. The directed fishery resumed again in 2014/15 with a TAC of 300 t ( 0.655 million pounds), but the fishery performance was relatively poor with a retained catch of 140 t ( 0.309 million pounds). The retained catch in 2015/16 was even lower at 48 t ( 0.105 million pounds) and the fishery has remained closed since 2016/17.
3. Stock biomass: The 1975-2018 NMFS trawl survey mean biomass is $5,664 \mathrm{t}$ with the 2018 value being the 5th lowest ( $1,731 \mathrm{t}$; the third lowest since 2000). This 2018 biomass of $\geq 90 \mathrm{~mm}$ carapace length (CL) male crab is $31 \%$ of the long term mean at 3.814 million pounds (with a CV of $28 \%$ ) is $31 \%$ of the long term mean. The most recent 3 -year average of the NMFS survey is $41 \%$ of the mean value, further indicating a decline in biomass compared to historical survey estimates, notably in 2010 and 2011 that were over six times the current average. The ADFG pot survey was repeated in 2018 and the relative biomass in this index was the lowest in the time series ( $12 \%$ of the mean from the 11 surveys conducted since 1995). The assessment model estimates dampen the interannual variability observed in the survey biomass and suggest that the stock (in survey biomass units) is presently at about $28 \%$ of the long term model-predicted survey biomass average. The trend from these values suggests a slight decline.
4. Recruitment: Recruitment is based on estimated number of male crab within the $90-104 \mathrm{~mm}$ CL size class in each year. The 2018 trawl-survey area-swept estimate of 0.154 million male SMBKC in this size class is the third lowest in the 41 years since 1978 and follows the lowest previously observed in 2017. The recent six-year (2013-2018) average recruitment is only $45 \%$ of this mean. In the pot-survey, the abundance of this size group in 2017 was also the second-lowest in the time series ( $22 \%$ of the mean for the available pot-survey data) whereas in 2018 the value was the lowest observed at only $10 \%$ of the mean value.
5. Management performance: In this assessment estimated total male catch is the sum of fisheryreported retained catch, estimated male discard mortality in the directed fishery, and estimated male bycatch mortality in the groundfish fisheries. Based on the reference model for SMBKC, the estimate for mature male biomass is below the minimum stock-size threshold (MSST) in 2017/18 and is hence is in an "overfished" condition, despite fishery closures in the last two years (and hence overfishing has not occurred) (Tables 1 and 2). Computations which indicate the relative impact of fishing (i.e., the

[^6]"dynamic $B_{0}$ ") suggests that the current spawning stock biomass has been reduced to $60 \%$ of what it would have been in the absence of fishing.

Table 1: Status and catch specifications (1000 t) for the reference model. A - calculated from the assessment reviewed by the Crab Plan Team in September 2014, B - calculated from the assessment reviewed by the Crab Plan Team in September 2015, C - calculated from the assessment reviewed by the Crab Plan Team in September 2016, D - calculated from the assessment reviewed by the Crab Plan Team in September 2017, E calculated from the assessment reviewed by the Crab Plan Team in September 2018.

6. Basis for the OFL: Estimated mature-male biomass (MMB) on 15 February is used as the measure of biomass for this Tier 4 stock, with males measuring $\geq 105 \mathrm{~mm}$ CL considered mature. The $B_{M S Y}$ proxy is obtained by averaging estimated MMB over a specific reference period, and current CPT/SSC guidance recommends using the full assessment time frame as the default reference period (Table 3).

Table 3: Basis for the OFL (1000 t) from the reference model.

## A. Summary of Major Changes

## Changes in Management of the Fishery

There are no new changes in management of the fishery.

## Changes to the Input Data

Data used in this assessment have been updated to include the most recently available fishery and survey numbers. This assessment makes use of two new survey data points including the 2018 NMFS trawl-survey estimate of abudance, and the 2018 ADF\&G pot survey CPUE. Both of these surveys have associated size compositon data. The assessment also uses updated 2010-2017 groundfish and fixed gear bycatch estimates based on NMFS Alaska Regional Office (AKRO) data. The directed fishery has been closed since 2016/17 so fishery data in recent years are unavailable.

## Changes in Assessment Methodology

This assessment uses the General model for Alasks crab stocks (Gmacs) framework. The model is configured to track three stages of length categories and was first presented in May 2011 by Bill Gaeuman and accepted by the CPT in May 2012. A difference from the original approach, and that used here, is that natural and fishing mortality are continuous within 5 discrete seasons (using the appropriate catch equation rather than assuming an applied pulse removal). Season length in Gmacs is controlled by changing the proportion of natural mortality that is applied each season. Diagnostic output includes estimates of the "dynamic $B_{0}$ " which simply computes the ratio of the spawning biomass as estimated relative to the spawning biomass that would have occurred had there been no historical fishing mortality. Details of this implementation and other model details are provided in Appendix A.

## Changes in Assessment Results

Both surveys indicate a decline over the past few years. The "reference" model is that which was selected for use in 2017. The addition of new data introduced this year area are presented sequentially. Two alternative models are presented for sensitivity. One involves a re-analysis of the NMFS trawl survey data using a spatio-temporal Delta-GLMM approach (VAST model; Thorson and Barnett 2017) and the other configuration (named "Fit survey") simply adds emphasis on the design-based survey data (by assuming a lower input variance). The VAST model suggests a modest increase from the 2017 survey estimate. However, the model tends to moderate the noise in the survey observations and declines

## B. Responses to SSC and CPT Comments

## CPT and SSC Comments on Assessments in General

Comment: Regarding general code development, the SSC and CPT outstanding requests continue to be as follows:

1. add the ability to conduct retrospective analyses

Progress was limited in implementing this feature.
2. add ability to estimate bycatch fishing mortality rates when observer data are missing but effort data is available

This was completed.
3. Continued exploration of data weighting (Francis and other approaches) and evaluation of models with and without the 1998 natural mortality spike. The authors are encouraged to bring other models forward for CPT and SSC consideration

We continued to include an alternative time series estimated from the NMFS trawl survey using the VAST spatiotemporal Delta GLMM model and continued with the iterative re-weighting for composition data.

## C. Introduction

## Scientific Name

The blue king crab is a lithodid crab, Paralithodes platypus (Brant 1850).

## Distribution

Blue king crab are sporadically distributed throughout the North Pacific Ocean from Hokkaido, Japan, to southeastern Alaska (Figure 1). In the eastern Bering Sea small populations are distributed around St. Matthew Island, the Pribilof Islands, St. Lawrence Island, and Nunivak Island. Isolated populations also exist in some other cold water areas of the Gulf of Alaska (NPFMC 1998). The St. Matthew Island Section for blue king crab is within Area Q2 (Figure 2), which is the Northern District of the Bering Sea king crab registration area and includes the waters north of Cape Newenham ( $58^{\circ} 39^{\prime} \mathrm{N}$. lat.) and south of Cape Romanzof ( $61^{\circ} 49^{\prime}$ N. lat.).

## Stock Structure

The Alaska Department of Fish and Game (ADF\&G) Gene Conservation Laboratory, has detected regional population differences between blue king crab collected from St. Matthew Island and the Pribilof Islands ${ }^{2}$. NMFS tag-return data from studies on blue king crab in the Pribilof Islands and St. Matthew Island support the idea that legal-sized males do not migrate between the two areas (Otto and Cummiskey 1990). St. Matthew Island blue king crab tend to be smaller than their Pribilof conspecifics, and the two stocks are managed separately.

## Life History

Like the red king crab, Paralithodes camtshaticus, the blue king crab is considered a shallow water species by comparison with other lithodids such as golden king crab, Lithodes aequispinus, and the scarlet king crab, Lithodes couesi (Donaldson and Byersdorfer 2005). Adult male blue king crab are found at an average depth of 70 m (NPFMC 1998). The reproductive cycle appears to be annual for the first two reproductive cycles and biennial thereafter (Jensen and Armstrong 1989), and mature crab seasonally migrate inshore where they molt and mate. Unlike red king crab, juvenile blue king crab do not form pods, but instead rely on cryptic coloration for protection from predators and require suitable habitat such as cobble and shell hash. Somerton and MacIntosh (1983) estimated SMBKC male size at sexual maturity to be 77 mm carapace length (CL). Paul et al. (1991) found that spermatophores were present in the vas deferens of $50 \%$ of the St. Matthew Island blue king crab males examined with sizes of $40-49 \mathrm{~mm}$ CL and in $100 \%$ of the males at least 100 mm CL. Spermataphore diameter also increased with increasing CL with an asymptote at $\sim 100 \mathrm{~mm}$ CL. It was noted, however, that although spermataphore presence indicates physiological sexual maturity, it may not be an indicator of functional sexual maturity. For purposes of management of the St. Matthew Island blue king crab fishery, the State of Alaska uses 105 mm CL to define the lower size bound of functionally mature males (Pengilly and Schmidt 1995). Otto and Cummiskey (1990) report an average growth increment of 14.1 mm CL for adult SMBKC males.

## Management History

The SMBKC fishery developed subsequent to baseline ecological studies associated with oil exploration (Otto 1990). Ten U.S. vessels harvested 545 t ( 1.202 million pounds) in 1977, and harvests peaked in 1983 when 164 vessels landed $4,288 \mathrm{t}$ ( 9.454 million pounds) (Fitch et al. 2012; Table 7).

[^7]The fishing seasons were generally short, often lasting only a few days. The fishery was declared overfished and closed in 1999 when the stock biomass estimate was below the minimum stock-size threshold (MSST) of $4,990 \mathrm{t}$ ( 11.0 million pounds) as defined by the Fishery Management Plan (FMP) for the Bering Sea/Aleutian Islands King and Tanner crabs (NPFMC 1999). Zheng and Kruse (2002) hypothesized a high level of SMBKC natural mortality from 1998 to 1999 as an explanation for the low catch per unit effort (CPUE) in the 1998/99 commercial fishery and the low numbers across all male crab size groups caught in the annual NMFS eastern Bering Sea trawl survey from 1999 to 2005 (see survey data in next section). In November 2000, Amendment 15 to the FMP for Bering Sea/Aleutian Islands king and Tanner crabs was approved to implement a rebuilding plan for the SMBKC stock (NPFMC 2000). The rebuilding plan included a State of Alaska regulatory harvest strategy ( $5 A A C 34.917$ ), area closures, and gear modifications. In addition, commercial crab fisheries near St. Matthew Island were scheduled in fall and early winter to reduce the potential for bycatch mortality of vulnerable molting and mating crab.

NMFS declared the stock rebuilt on 21 September 2009, and the fishery was reopened after a 10-year closure on 15 October 2009 with a TAC of 529 t ( 1.167 million pounds), closing again by regulation on 1 February 2010. Seven participating vessels landed a catch of 209 t ( 0.461 million pounds) with a reported effort of 10,697 pot lifts and an estimated CPUE of 9.9 retained individual crab per pot lift. The fishery remained open the next three years with modest harvests and similar CPUE, but large declines in the NMFS trawl-survey estimate of stock abundance raised concerns about the health of the stock. This prompted ADF\&G to close the fishery again for the $2013 / 14$ season. The fishery was reopened for the $2014 / 15$ season with a low TAC of 297 t ( 0.655 million pounds) and in $2015 / 16$ the TAC was further reduced to 186 t ( 0.411 million pounds) then completely closed during the 2016/17 season.

Although historical observer data are limited due to low sampling effort, bycatch of female and sublegal male crab from the directed blue king crab fishery off St. Matthew Island was relatively high historically, with estimated total bycatch in terms of number of crab captured sometimes more than twice as high as the catch of legal crab (Moore et al. 2000; ADF\&G Crab Observer Database). Pot-lift sampling by ADF\&G crab observers (Gaeuman 2013; ADF\&G Crab Observer Database) indicates similar bycatch rates of discarded male crab since the reopening of the fishery (Table 5), with total male discard mortality in the 2012/13 directed fishery estimated at about $12 \%$ ( 88 t or 0.193 million pounds) of the reported retained catch weight, assuming $20 \%$ handling mortality.

These data suggest a reduction in the bycatch of females, which may be attributable to the later timing of the contemporary fishery and the more offshore distribution of fishery effort since reopening in 2009/10 ${ }^{3}$. Some bycatch of discarded blue king crab has also been observed historically in the eastern Bering Sea snow crab fishery, but in recent years it has generally been negligible. The St. Matthew Island golden king crab fishery, the third commercial crab fishery to have taken place in the area, typically occurred in areas with depths exceeding blue king crab distribution. The NMFS observer data suggest that variable, but mostly limited, SMBKC bycatch has also occurred in the eastern Bering Sea groundfish fisheries (Table 6).

## D. Data

## Summary of New Information

Data used in this assessment were updated to include the most recently available fishery and survey numbers. This assessment makes use of two new survey data points including the 2018 NMFS trawl-survey estimate of abudance, and the 2018 ADF\&G pot survey CPUE. Both of these surveys have associated size compositon data. The assessment also uses updated 1993-2016 groundfish and fixed gear bycatch estimates based on AKRO data. The fishery was closed in $2016 / 17$ so no directed fishery catch data were available. The data used in each of the new models is shown in Figure 3.

[^8]
## Major Data Sources

Major data sources used in this assessment include annual directed-fishery retained-catch statistics from fish tickets (1978/79-1998/99, 2009/10-2012/13, and 2014/15-2015/16; Table 7); results from the annual NMFS eastern Bering Sea trawl survey (1978-2018; Table 8); results from the ADF\&G SMBKC pot survey (every third year during 1995-2013, then 2015-2018; Table 9); mean somatic mass given length category by year (Table 10); size-frequency information from ADF\&G crab-observer pot-lift sampling (1990/91-1998/99, 2009/10-2012/13, and 2014/15-2016/17; Table 5); and the NMFS groundfish-observer bycatch biomass estimates (1992/93-2016/17; Table 6).

Figure 4 maps stations from which SMBKC trawl-survey and pot-survey data were obtained. Further information concerning the NMFS trawl survey as it relates to commercial crab species is available in Daly et al. (2014); see Gish et al. (2012) for a description of ADF\&G SMBKC pot-survey methods. It should be noted that the two surveys cover different geographic regions and that each has in some years encountered proportionally large numbers of male blue king crab in areas not covered by the other survey (Figure 5). Crab-observer sampling protocols are detailed in the crab-observer training manual (ADF\&G 2013). Groundfish SMBKC bycatch data come from the NMFS Regional office and have been compiled to coincide with the SMBKC management area.

## Other Data Sources

The growth transition matrix used is based on Otto and Cummiskey (1990), as in the past. Other relevant data sources, including assumed population and fishery parameters, are presented in Appendix A, which also provides a detailed description of the model configuration used for this assessment.

## E. Analytic Approach

## History of Modeling Approaches for this Stock

A four-stage catch-survey-analysis (CSA) assessment model was used before 2011 to estimate abundance and biomass and prescribe fishery quotas for the SMBKC stock. The four-stage CSA is similar to a full length-based analysis, the major difference being coarser length groups, which are more suited to a small stock with consistently low survey catches. In this approach, the abundance of male crab with a CL $\geq 90 \mathrm{~mm}$ is modeled in terms of four crab stages: stage 1: 90-104 mm CL; stage 2: 105-119 mm CL; stage 3: newshell $120-133 \mathrm{~mm}$ CL; and stage 4: oldshell $\geq 120 \mathrm{~mm}$ CL and newshell $\geq 134 \mathrm{~mm}$ CL. Motivation for these stage definitions comes from the fact that for management of the SMBKC stock, male crab measuring $\geq 105 \mathrm{~mm}$ CL are considered mature, whereas 120 mm CL is considered a proxy for the legal size of 5.5 in carapace width, including spines. Additional motivation for these stage definitions comes from an estimated average growth increment of about 14 mm per molt for SMBKC (Otto and Cummiskey 1990).
Concerns about the pre-2011 assessment model led to the CPT and SSC recommendations that included development of an alternative model with provisional assessment based on survey biomass or some other index of abundance. An alternative 3-stage model was proposed to the CPT in May 2011, but a survey-based approach was requested for the Fall 2011 assessment. In May 2012 the CPT approved a slightly revised and better documented version of the alternative model for assessment. Subsequently, the model developed and used since 2012 was a variant of the previous four-stage SMBKC CSA model and similar in complexity to that described by Collie et al. (2005). Like the earlier model, it considered only male crab $\geq 90 \mathrm{~mm}$ in CL, but combined stages 3 and 4 of the earlier model, resulting in three stages (male size classes) defined by CL measurements of (1) 90-104 mm, (2) 105-119 mm, and (3) $120 \mathrm{~mm}+$ (i.e., 120 mm and above). This consolidation was driven by concern about the accuracy and consistency of shell-condition information, which had been used in distinguishing stages 3 and 4 of the earlier model.

In 2016 the accepted SMBKC assessment model made use of the modeling framework Gmacs (Webber et al. 2016). In that assessment, an effort was made to match the 2015 SMBKC stock assessment model to bridge a framework which provided greater flexibility and opportunity to evaluate model assumptions more fully.

## Assessment Methodology

This assessment model again uses the modeling framework Gmacs and is detailed in Appendix A.

## Model Selection and Evaluation

Five models were presented in the previous assessment. This year, four models are presented with the reference model being the same configuration as approved last year (Ianelli et al. 2017), two sensitivities are considered, one with a different treatment of NMFS bottom trawl survey (BTS) data using a geo-spatial model (VAST; Thorson and Barnett 2017; Appendix C). A second sensitivity was constructed which weights the survey data more heavily. In addition to these sensitivities, we evaluated the impacts of adding new data to the reference model. In summary, the following lists the models presented and the naming convention used:

1. 2017 Model: the 2017 recommended model without any new data
2. BTS: adds in the 2018 bottom trawl survey (BTS) data
3. BTS and pot: as with previous but including the 2018 ADFG pot survey data (Model 16.0 or "reference case")
4. VAST: applies a geo-spatial delta-GLMM model (Thorson and Barnett 2017) to the BTS data which provides a different BTS index. See appendix B for details and diagnostics. This is a preliminary examination as more work is needed to ensure options for the BTS CPUE data were specified appropriately.
5. Fit survey: an exploratory scenario that's the same as the reference model except the NMFS trawl survey is up-weighted by $\lambda^{\text {NMFS }}=2$ and the $A D F \& G$ pot survey is up-weighted by $\lambda^{\text {ADFG }}=2$.
Note that SSC convention would label these (item 3 above) as model 16.0 (the model first developed in that year). Since only a few models are presented here, for simplicity we labeled model 16.0 as "reference" and for the others, we used the simple naming convention presented above.

## Results

## a. Sensitivity to new data

Results for scenarios are provided with comparisons to the 2017 model and sensitivity new data are shown in Figures 6 and 7 with recruitment and spawning biomass shown in Figures 8 and 9, respectively. The fits to survey CPUEs and spawning biomass show that the addition of new data results in more of a decline than in the 2017 assessment, especially with the addition of the pot survey.

## b. Alternative NMFS bottom-trawl survey index

Results comparing model fits between the VAST model and the reference case show different time-series of data and a different model fit (Figure 10). The effect on spawning biomass suggests estimates were consistently higher since 1990 compared to the reference model (Figure 11).

## c. Effective sample sizes and weighting factors

Observed and estimated effective sample sizes are compared in Table 11. Data weighting factors, standard deviation of normalized residuals (SDNRs), and median absolute residual (MAR) are presented in Table 16. The SDNR for the trawl survey is acceptable at 1.66 in the reference model. Francis (2011) weighting was applied in 2017 but given the relatively few size bins in this assessment, this application was suspended this year.
The SDNRs for the pot surveys show a similar pattern in each of the scenarios, but are much higher suggesting an inconsistency between the pot survey data and the model structure and other data components. Rather than re-weighting, we chose to retain the values as specified, noting that down-weighting these data would effectively exclude the signal from this series. The MAR values for the trawl and pot surveys shows the same pattern among each of the scenarios as the SDNR. The SDNR and MAR values for the trawl survey and pot survey size compositions were relatively good, ranging from 0.54 to 0.73 for the reference case. The SDNRs for the directed pot fishery and other size compositions were similar to previous estimates.

## d. Parameter estimates

Model parameter estimates for each of the Gmacs scenarios are summarized in Tables 12, 13, and 15. These parameter estimates are compared in Table 15. Negative log-likelihood values and management measures for each of the model configurations are compared in Tables 4 through 17.

There are some differences in parameter estimates among models as reflected in the log-likelihood components and the management quantities. The parameter estimates in the "fit survey" scenario differ the most, as expected, particularly the estimate of the ADF\&G pot survey catchability (q) (see Table 15). Also, the residuals for recruitment in the first size group are large for these model runs, presumably because higher estimates of recruits in some years are required by the model to match the observed biomass trends.

Selectivity estimates show some variability between models (Figure 12). Estimated recruitment is variable over time for all models and in recent years is well below average (Figure 13). Estimated mature male biomass on 15 February also fluctuates considerably (Figure 14). Estimated natural mortality each year $\left(M_{t}\right)$ is presented in Figure 15.

## e. Evaluation of the fit to the data.

The model fits to total male ( $\geq 90 \mathrm{~mm}$ CL) trawl survey biomass tend to miss the recent peak around 2010 and is slightly above the 2017 value for the key sensitivities (Figures 16). All of the models fit the pot survey CPUE poorly (Figure 17. For both surveys the standardized residuals tend to have similar patterns with some improvement (generally) for the VAST model (Figures 18 and 19).
Fits to the size compositions for trawl survey, pot survey, and commercial observer data are reasonable but miss the largest size category in some years (Figures 20, 21, and 22) for all scenarios. Representative residual plots of the composition data fits are generally poor (Figures 23 and 24 ). The model fits to different types of retained and discarded catch values performed as expected given the assumed levels of uncertainty on the input data (Figure 25 ).

Unsurprisingly, the Fit surveys model fits the the NMFS survey biomass and ADF\&G pot survey CPUE data better but still has a similar residual pattern (Figures 16 and 17). It is worth noting that that this scenario (included for exploratory purposes) resulted in worse SDNR and MAR values for the two abundance indices.

## f. Retrospective and historical analyses

This is only the second year a formal assessment model developed for this stock. As such, retrospective patterns and historical analyses relative to fisheries impacts are limited.

## g. Uncertainty and sensitivity analyses.

Estimated standard deviations of parameters and selected management measures for the models are summarized in Tables 12, 13, and 14 (compiled in Table 15). Probabilities for mature male biomass and OFL in 2017 are presented in Section F.

## h. Comparison of alternative model scenarios.

The estimates of mature male biomass (Figure 14), for the Fit survey sensitivity differs from the other models due to a low value for pot survey catchability being estimated (which tends to scale the population estimate). This existng scenario results in a lower MMB from the mid-1980s through to the late-1990s, and is again lower in the most recent 5 years. This scenario upweights both the trawl and pot surveys abundance indices and represents a model run that places greater emphasis on the abundance indices.

In summary, the use of the reference model for management purposes is preferred since it provides the best fit to the data and is consistent with previous model specifications. Research on alternative model specifications (e.g., natural mortality variability) was limited this year. The VAST model may take better account of spatial processes but requires more research to ensure it has been appropriately applied and the assumptions are reasonable. Consequently, the reference model appears reasonable and appropriate for ACL and OFL determinations for this stock in 2017. Nonetheless, the Fit surveys model, while difficult to statistically justify, portends a more dire stock status (see below) and should highlight the caution needed in managing this resource.

## F. Calculation of the OFL and ABC

The overfishing level (OFL) is the fishery-related mortality biomass associated with fishing mortality $F_{O F L}$. The SMBKC stock is currently managed as Tier 4, and only a Tier 4 analysis is presented here. Thus given stock estimates or suitable proxy values of $B_{M S Y}$ and $F_{M S Y}$, along with two additional parameters $\alpha$ and $\beta$, $F_{O F L}$ is determined by the control rule

$$
\begin{align*}
& F_{O F L}= \begin{cases}F_{M S Y}, & \text { when } B / B_{M S Y}>1 \\
F_{M S Y} \frac{\left(B / B_{M S Y}-\alpha\right)}{(1-\alpha)}, & \text { when } \beta<B / B_{M S Y} \leq 1\end{cases}  \tag{1}\\
& F_{O F L}<F_{M S Y} \text { with directed fishery } F=0 \text { when } B / B_{M S Y} \leq \beta
\end{align*}
$$

where $B$ is quantified as mature-male biomass (MMB) at mating with time of mating assigned a nominal date of 15 February. Note that as $B$ itself is a function of the fishing mortality $F_{O F L}$ (therefore numerical approximation of $F_{O F L}$ is required). As implemented for this assessment, all calculations proceed according to the model equations given in Appendix A. $F_{O F L}$ is taken to be full-selection fishing mortality in the directed pot fishery and groundfish trawl and fixed-gear fishing mortalities set at their model geometric mean values over years for which there are data-based estimates of bycatch-mortality biomass.

The currently recommended Tier 4 convention is to use the full assessment period, currently 1978-2018, to define a $B_{M S Y}$ proxy in terms of average estimated MMB and to set $\gamma=1.0$ with assumed stock natural mortality $M=0.18 \mathrm{yr}^{-1}$ in setting the $F_{M S Y}$ proxy value $\gamma M$. The parameters $\alpha$ and $\beta$ are assigned their default values $\alpha=0.10$ and $\beta=0.25$. The $F_{O F L}$, $\mathrm{OFL}, \mathrm{ABC}$, and MMB in 2018 for all scenarios are summarized in Table 4. The ABC is $80 \%$ of the OFL.

## G. Rebuilding Analysis

This stock is not currently subject to a rebuilding plan. However, interpretation of the point estimate for the reference case suggests that the mature male biomass is below $50 \%$ of $B_{M S Y}$ but slightly above for the "VAST" model configuration (Table 4 ).

Table 4: Comparisons of management measures for the model scenarios. Biomass and OFL are in tons.

| Component | Reference | VAST | Fit surveys |
| :--- | ---: | ---: | ---: |
| $\mathrm{MMB}_{2018}$ | 1309.025 | 2257.996 | 4038.448 |
| $B_{\mathrm{MSY}}$ | 3698.941 | 4240.714 | 9161.159 |
| $F_{\mathrm{OFL}}$ | 0.043 | 0.075 | 0.059 |
| $\mathrm{OFL}_{2018}$ | 38.464 | 117.589 | 191.950 |
| $\mathrm{ABC}_{2018}$ | 30.771 | 94.072 | 153.560 |

## H. Data Gaps and Research Priorities

The following topics have been listed as areas where more research on SMBKC is needed:

1. Growth increments and molting probabilities as a function of size.
2. Trawl survey catchability and selectivities.
3. Temporal changes in spatial distributions near the island.
4. Natural mortality.

## I. Projections and outlook

The outlook for recruitment is pessimistic and the abundance relative to the proxy $B_{M S Y}$ is low. The NMFS survey results in 2018 noted ocean conditions warmer than normal with an absence of a "cold pool" in the region. This could have detrimental effects on the SMBKC stocks and should be carefully monitored. Relative to the impact of historical fishing, we again conducted a "dynamic- $B_{0}$ " analysis. This procedure simply projects the population based on estimated recruitment but removes the effect of fishing. For the reference case, this suggests that the impact of fishing has reduced to stock to about $60 \%$ of what it would have been in the absence of fishing (Figure 26) . The other non-fishing contributors to the observed depleted stock trend (ignoring stock-recruit relationship) may reflect variable survival rates due to environmental conditions and also range shifts.

## J. Acknowledgements

We thank the Crab Plan Team and AFSC staff for reviewing an earlier draft of this report and Andre Punt for his input into refinements to the Gmacs model code.

Table 16: Comparisons of data weights, Francis LF weights (i.e. the new weights that should be applied to the LFs), SDNR and MAR (standard deviation of normalized residuals and median absolute residual) values for the model scenarios.

| Component | Reference | VAST | Fit surveys |
| :--- | ---: | ---: | ---: |
| NMFS trawl survey weight | 1.00 | 1.00 | 2.00 |
| ADF\&G pot survey weight | 1.00 | 1.00 | 2.00 |
| Directed pot LF weight | 1.00 | 1.00 | 1.00 |
| NMFS trawl survey LF weight | 1.00 | 1.00 | 1.00 |
| ADF\&G pot survey LF weight | 1.00 | 1.00 | 1.00 |
| Fancis weight for directed pot LF | 1.47 | 1.43 | 1.15 |
| Francis weight for NMFS trawl survey LF | 0.42 | 0.38 | 0.30 |
| Francis weight for ADF\&G pot survey LF | 1.01 | 0.88 | 0.18 |
| SDNR NMFS trawl survey | 1.66 | 1.97 | 2.66 |
| SDNR ADF\&G pot survey | 4.51 | 4.82 | 7.83 |
| SDNR directed pot LF | 0.90 | 0.93 | 1.19 |
| SDNR NMFS trawl survey LF | 1.35 | 1.44 | 1.93 |
| SDNR ADF\&G pot survey LF | 1.02 | 1.08 | 2.35 |
| MAR NMFS trawl survey | 1.21 | 1.10 | 1.99 |
| MAR ADF\&G pot survey | 2.81 | 2.74 | 4.75 |
| MAR directed pot LF | 0.70 | 0.64 | 0.68 |
| MAR NMFS trawl survey LF | 0.54 | 0.67 | 1.06 |
| MAR ADF\&G pot survey LF | 0.70 | 0.97 | 2.03 |

Table 17: Comparisons of negative log-likelihood values for the selected model scenarios. It is important to note that comparisons among models may be limited since the assumed variances are modified (e.g., Fit surveys model).

| Component | Reference | VAST | Fit surveys |
| :--- | ---: | ---: | ---: |
| Pot Retained Catch | -73.35 | -72.70 | -68.87 |
| Pot Discarded Catch | 33.61 | 16.32 | 112.35 |
| Trawl bycatch Discarded Catch | -7.43 | -7.36 | -7.43 |
| Fixed bycatch Discarded Catch | -7.41 | -7.33 | -7.40 |

Figure 20: Observed and model estimated size-frequencies of SMBKC by year retained in the directed pot fishery for the model scenarios.

Figure 21: Observed and model estimated size-frequencies of discarded male SMBKC by year in the NMFS trawl survey for the model scenarios.

Figure 22: Observed and model estimated size-frequencies of discarded SMBKC by year in the ADF\&G pot survey for the model scenarios.

Figure 23: Bubble plots of residuals by stage and year for the directed pot fishery size composition data for SMBKC in the reference model.

Figure 24: Bubble plots of residuals by stage and year for the ADF\&G pot survey size composition data for SMBKC in the fit surveys model.

Figure 25: Comparison of observed and model predicted retained catch and bycatches in each of the Gmacs models. Note that difference in units between each of the panels, some panels are expressed in numbers of crab, some as biomass (tons).

Figure 26: Comparisons of mature male biomass relative to the dynamic $B_{0}$ value, ( 15 February, 1978-2018) for each of the model scenarios.

## Appendix A: SMBKC Model Description

## 1. Introduction

The Gmacs model has been specified to account only for male crab $\geq 90 \mathrm{~mm}$ in carapace length (CL). These are partitioned into three stages (size- classes) determined by CL measurements of (1) 90-104 mm, (2) 105-119 mm , and (3) $120+\mathrm{mm}$. For management of the St. Matthew Island blue king crab (SMBKC) fishery, 120 mm CL is used as the proxy value for the legal measurement of 5.5 inch carapace width (CW), whereas 105 mm CL is the management proxy for mature-male size (state regulation $5 A A C 34.917$ (d)). Accordingly, within the model only stage- 3 crab are retained in the directed fishery, and stage- 2 and stage- 3 crab together comprise the collection of mature males. Some justification for the 105 mm value is presented in Pengilly and Schmidt (1995), who used it in developing the current regulatory SMBKC harvest strategy. The term "recruit" here designates recruits to the model, i.e., annual new stage-1 crab, rather than recruits to the fishery. The following description of model structure reflects the Gmacs base model configuration.

## 2. Model Population Dynamics

Within the model, the beginning of the crab year is assumed contemporaneous with the NMFS trawl survey, nominally assigned a date of 1 July. Although the timing of the fishery is different each year, MMB is estimated at 15 February, which is the reference date for calculation of federal management biomass quantities. To accommodate this, each model year is split into 5 seasons $(t)$ and a proportion of the natural mortality $\left(\tau_{t}\right)$, scaled relative to the portions of the year, is applied in each of these seasons where $\sum_{t=1}^{t=5} \tau_{t}=1$. Each model year consists of the following processes with time-breaks denoted here by "Seasons." However, it is important to note that actual seasons are survey-to-fishery, fishery-to Feb 15, and Feb 15 to July 1. The following breakdown accounts for events and fishing mortality treatments:

1. Season 1 (survey period)

- Beginning of the SMBKC fishing year (1 July)
- $\tau_{1}=0$
- Surveys

2. Season 2 (natural mortality until pulse fishery)

- $\tau_{2}$ ranges from 0.05 to 0.44 depending on the time of year the fishery begins each year (i.e., a higher value indicates the fishery begins later in the year; see Table 7)

3. Season 3 (pulse fishery)

- $\tau_{3}=0$
- fishing mortality applied

4. Season 4 (natural mortality until spawning)

- $\tau_{4}=0.63-\sum_{i=1}^{i=4} \tau_{i}$
- Calculate MMB (15 February)

5. Season 5 (natural mortality and somatic growth through to June 30th)

- $\tau_{5}=0.37$
- Growth and molting
- Recruitment (all to stage-1)

The proportion of natural mortality $\left(\tau_{t}\right)$ applied during each season in the model is provided in Table 22. The beginning of the year ( 1 July) to the date that MMB is measured ( 15 February) is $63 \%$ of the year. Therefore $63 \%$ of the natural mortality must be applied before the MMB is calculated. Because the timing of the fishery is different each year, $\tau_{2}$ varies and thus $\tau_{4}$ varies also.

With boldface lower-case letters indicating vector quantities we designate the vector of stage abundances during season $t$ and year $y$ as

$$
\begin{equation*}
\boldsymbol{n}_{t, y}=n_{l, t, y}=\left[n_{1, t, y}, n_{2, t, y}, n_{3, t, y}\right]^{\top} . \tag{2}
\end{equation*}
$$

The number of new crab, or recruits, of each stage entering the model each season $t$ and year $y$ is represented as the vector $\boldsymbol{r}_{t, y}$. The SMBKC formulation of Gmacs specifies recruitment to stage- 1 only during season $t=5$, thus the recruitment size distribution is

$$
\begin{equation*}
\phi_{l}=[1,0,0]^{\top}, \tag{3}
\end{equation*}
$$

and the recruitment is

$$
\boldsymbol{r}_{t, y}= \begin{cases}0 & \text { for } \quad t<5  \tag{4}\\ \bar{R} \phi_{l} \delta_{y}^{R} & \text { for } \quad t=5\end{cases}
$$

where $\bar{R}$ is the average annual recruitment and $\delta_{y}^{R}$ are the recruitment deviations each year $y$

$$
\begin{equation*}
\delta_{y}^{R} \sim \mathcal{N}\left(0, \sigma_{R}^{2}\right) \tag{5}
\end{equation*}
$$

Using boldface upper-case letters to indicate a matrix, we describe the size transition matrix $\boldsymbol{G}$ as

$$
\boldsymbol{G}=\left[\begin{array}{ccc}
1-\pi_{12}-\pi_{13} & \pi_{12} & \pi_{13}  \tag{6}\\
0 & 1-\pi_{23} & \pi_{23} \\
0 & 0 & 1
\end{array}\right],
$$

with $\pi_{j k}$ equal to the proportion of stage- $j$ crab that molt and grow into stage- $k$ within a season or year.
The natural mortality each season $t$ and year $y$ is

$$
\begin{equation*}
M_{t, y}=\bar{M} \tau_{t}+\delta_{y}^{M} \text { where } \delta_{y}^{M} \sim \mathcal{N}\left(0, \sigma_{M}^{2}\right) \tag{7}
\end{equation*}
$$

Fishing mortality by year $y$ and season $t$ is denoted $F_{t, y}$ and calculated as

$$
\begin{equation*}
F_{t, y}=F_{t, y}^{\mathrm{df}}+F_{t, y}^{\mathrm{tb}}+F_{t, y}^{\mathrm{fb}} \tag{8}
\end{equation*}
$$

where $F_{t, y}^{\mathrm{df}}$ is the fishing mortality associated with the directed fishery, $F_{t, y}^{\mathrm{tb}}$ is the fishing mortality associated with the trawl bycatch fishery, $F_{t, y}^{\mathrm{fb}}$ is the fishing mortality associated with the fixed bycatch fishery. Each of these are derived as

$$
\begin{array}{lll}
F_{t, y}^{\mathrm{df}}=\bar{F}^{\mathrm{df}}+\delta_{t, y}^{\mathrm{df}} & \text { where } & \delta_{t, y}^{\mathrm{df}} \sim \mathcal{N}\left(0, \sigma_{\mathrm{df}}^{2}\right), \\
F_{t, y}^{\mathrm{tb}}=\bar{F}^{\mathrm{tb}}+\delta_{t, y}^{\mathrm{tb}} & \text { where } & \delta_{t, y}^{\mathrm{df}} \sim \mathcal{N}\left(0, \sigma_{\mathrm{tb}}^{2}\right), \\
F_{t, y}^{\mathrm{fb}}=\bar{F}^{\mathrm{fb}}+\delta_{t, y}^{\mathrm{fb}} & \text { where } & \delta_{t, y}^{\mathrm{df}} \sim \mathcal{N}\left(0, \sigma_{\mathrm{fb}}^{2}\right), \tag{9}
\end{array}
$$

where $\delta_{t, y}^{\mathrm{df}}, \delta_{t, \underline{y}}^{\mathrm{tb}}$, and $\delta_{t, y}^{\mathrm{fb}}$ are the fishing mortality deviations for each of the fisheries, each season $t$ during each year $y, \bar{F}^{\text {df }}, \bar{F}^{\text {tb }}$, and $\bar{F}^{\text {fb }}$ are the average fishing mortalities for each fishery. The total mortality $Z_{l, t, y}$ represents the combination of natural mortality $M_{t, y}$ and fishing mortality $F_{t, y}$ during season $t$ and year $y$

$$
\begin{equation*}
Z_{t, y}=Z_{l, t, y}=M_{t, y}+F_{t, y} \tag{10}
\end{equation*}
$$

The survival matrix $\boldsymbol{S}_{t, y}$ during season $t$ and year $y$ is

$$
\boldsymbol{S}_{t, y}=\left[\begin{array}{ccc}
1-e^{-Z_{1, t, y}} & 0 & 0  \tag{11}\\
0 & 1-e^{-Z_{2, t, y}} & 0 \\
0 & 0 & 1-e^{-Z_{3, t, y}}
\end{array}\right]
$$

The basic population dynamics underlying Gmacs can thus be described as

$$
\begin{array}{lr}
\boldsymbol{n}_{t+1, y}=\boldsymbol{S}_{t, y} \boldsymbol{n}_{t, y}, & \text { if } t<5 \\
\boldsymbol{n}_{t, y+1}=\boldsymbol{G} \boldsymbol{S}_{t, y} \boldsymbol{n}_{t, y}+\boldsymbol{r}_{t, y} & \text { if } t=5
\end{array}
$$

## 3. Model Data

Data inputs used in model estimation are listed in Table 23.

## 4. Model Parameters

Table 24 lists fixed (externally determined) parameters used in model computations. In all scenarios, the stage-transition matrix is

$$
\boldsymbol{G}=\left[\begin{array}{ccc}
0.2 & 0.7 & 0.1  \tag{13}\\
0 & 0.4 & 0.6 \\
0 & 0 & 1
\end{array}\right]
$$

which is the combination of the growth matrix and molting probabilities.
Estimated parameters are listed in Table 25 and include an estimated natural mortality deviation parameter in 1998/99 ( $\delta_{1998}^{M}$ ) assuming an anomalous mortality event in that year, as hypothesized by Zheng and Kruse (2002), with natural mortality otherwise fixed at $0.18 \mathrm{yr}^{-1}$.

## 5. Model Objective Function and Weighting Scheme

The objective function consists of the sum of several "negative log-likelihood" terms characterizing the hypothesized error structure of the principal data inputs (Table 17). A lognormal distribution is assumed to characterize the catch data and is modelled as

$$
\begin{align*}
& \sigma_{t, y}^{\text {catch }}=\sqrt{\log \left(1+\left(C V_{t, y}^{\text {catch }}\right)^{2}\right)}  \tag{14}\\
& \delta_{t, y}^{\text {catch }}=\mathcal{N}\left(0,\left(\sigma_{t, y}^{\text {catch }}\right)^{2}\right) \tag{15}
\end{align*}
$$

where $\delta_{t, y}^{\text {catch }}$ is the residual catch. The relative abudance data is also assumed to be lognormally distributed

$$
\begin{align*}
\sigma_{t, y}^{\mathrm{I}} & =\frac{1}{\lambda} \sqrt{\log \left(1+\left(C V_{t, y}^{\mathrm{I}}\right)^{2}\right)}  \tag{16}\\
\delta_{t, y}^{\mathrm{I}} & =\log \left(I^{\mathrm{obs}} / I^{\mathrm{pred}}\right) / \sigma_{t, y}^{\mathrm{I}}+0.5 \sigma_{t, y}^{\mathrm{I}} \tag{17}
\end{align*}
$$

and the likelihood is

$$
\begin{equation*}
\sum \log \left(\delta_{t, y}^{\mathrm{I}}\right)+\sum 0.5\left(\sigma_{t, y}^{\mathrm{I}}\right)^{2} \tag{18}
\end{equation*}
$$

Gmacs calculates standard deviation of the normalised residual (SDNR) values and median of the absolute residual (MAR) values for all abundance indices and size compositions to help the user come up with resonable likelihood weights. For an abundance data set to be well fitted, the SDNR should not be much greater than 1 (a value much less than 1, which means that the data set is fitted better than was expected, is not a cause for concern). What is meant by "much greater than 1 " depends on $m$ (the number of years in the data set). Francis (2011) suggests upper limits of $1.54,1.37$, and 1.26 for $m=5,10$, and 20 , respectively. Although an SDNR not much greater than 1 is a necessary condition for a good fit, it is not sufficient. It is important to plot the observed and expected abundances to ensure that the fit is good.
Gmacs also calculates Francis weights for each of the size composition data sets supplied (Francis 2011). If the user wishes to use the Francis iterative re-weighting method, first the weights applied to the abundance indices should be adjusted by trial and error until the SDNR (and/or MAR) are adequte. Then the Francis weights supplied by Gmacs should be used as the new likelihood weights for each of the size composition data sets the next time the model is run. The user can then iteratively adjust the abudance index and size composition weights until adequate SDNR (and/or MAR) values are achieved, given the Francis weights.

## 6. Estimation

The model was implemented using the software AD Model Builder (Fournier et al. 2012), with parameter estimation by minimization of the model objective function using automatic differentiation. Parameter estimates and standard deviations provided in this document are AD Model Builder reported values assuming maximum likelihood theory asymptotics.

## Appendix C. Spatio-temporal analysis of NMFS bottom-trawl survey SMBKC data

## Overview

This application of vast was configured to model a subset of NMFS/AFSC bottom trawl survey data. Specifically, the station-specific CPUE (kg per hectare) for male crab great than or equal to 90 mm CW were
compiled from 1978-2018. Further details can be found at the GitHub repo mainpage, wiki, and glossary. The R help files, e.g., ?Data_Fn for explanation of data inputs, or ?Param_Fn for explanation of parameters. VAST has involved many publications for developing individual features (see references section below). What follows is intended as a step by step documentation of applying the model to these data.

## Model configuration

The following loads in the main libraries.

## Spatial settings

The following settings define the spatial resolution for the model, and whether to use a grid or mesh approximation as well as specific model settings.

## Data preparation

## Data-frame for catch-rate data

The following extracts a subset of the data file downloaded from AKFIN.

## Build and run model

To estimate parameters, first create a list of data-inputs used for parameter estimation. Data_Fn has some simple checks for buggy inputs, but also please read the help file ?Data_Fn.

## Diagnostic plots

## Convergence

Diagnostics generated during parameter estimation can confirm that parameter estimates are away from upper or lower bounds and that the final gradient for each fixed-effect is close to zero. For explanation of parameters, please see references (and specifically Data_Fn in R).

## Encounter-probability component

One can check to ensure that observed encounter frequencies for either low or high probability samples are within the $95 \%$ predictive interval for predicted encounter probability (Figure . Diagnostics for positive-catchrate component was evaluated using a standard Q-Q plot. Qualitatively, the fits to SMBKC are reasonable but could stand some more evaluation for improvement as only one configuration was tested here (Figures ?? and .

## Pearson residuals

Spatially the residual pattern can be evaluated over time. Results for SMBKC shows that consistent positive or negative residuals accross or within years is limited for the encounter probability component of the model and for the positive catch rate component (Figures 30 and 31, respectively). Some VAST plots for visualizing results can be seen by examining the direction of faster or slower spatial decorrelation (termed "geometric anisotropy"; Figure 32).

Figure 27: Observed encounter rates and predicted probabilities for SMBKC.

Figure 28: Plot indicating distribution of quantiles for "positive catch rate" component.

Figure 29: Quantile-quantile plot of residuals for "positive catch rate" component.

## Densities and biomass estimates

Relative densities over time suggests that the biomass of males $>89 \mathrm{~mm}$ are generally concentrated within the central part of the survey region (Figure 33). For the application to SMBKC, the biomass index was scaled to have the same mean as that from the design-based estimate ( $5,764 \mathrm{t}$ ) of abundance (Table 27).

Table 23: Data inputs used in model estimation.

| Data | Years | Source |
| :--- | :--- | :--- |
| Directed pot-fishery retained-catch number <br> (not biomass) | $1978 / 79-1998 / 99$ <br> $2009 / 10-2015 / 16$ | Fish tickets <br> (fishery closed 1999/00-2008/09 and 2016/17) |
| Groundfish trawl bycatch biomass | $1992 / 93-2016 / 17$ | NMFS groundfish observer program |
| Groundfish fixed-gear bycatch biomass | $1992 / 93-2016 / 17$ | NMFS groundfish observer program |
| NMFS trawl-survey biomass index <br> (area-swept estimate) and CV | $1978-2018$ | NMFS EBS trawl survey |
| ADF\&G pot-survey abundance index <br> (CPUE) and CV | ADF\&G SMBKC pot survey |  |
| NMFS trawl-survey stage proportions <br> and total number of measured crab | $1995-2017$ | NMFS EBS trawl survey |
| ADF\&G pot-survey stage proportions <br> and total number of measured crab | $1995-2017$ | ADF\&G SMBKC pot survey |
| Directed pot-fishery stage proportions <br> and total number of measured crab | $1990 / 91-1998 / 99$ | ADF\&G crab observer program |

Table 24: Fixed model parameters for all scenarios.

| Parameter | Symbol | Value | Source/rationale |
| :---: | :---: | :---: | :---: |
| Trawl-survey catchability | $q$ | 1.0 | Default |
| Natural mortality | M | $0.18 \mathrm{yr}^{-1}$ | NPFMC (2007) |
| Size transition matrix | G | Equation 13 | Otto and Cummiskey (1990) |
| Stage-1 and stage-2 mean weights | $w_{1}, w_{2}$ | $0.7,1.2 \mathrm{~kg}$ | Length-weight equation (B. Foy, NMFS) applied to stage midpoints |
| Stage-3 mean weight | $w_{3, y}$ | Depends on year Table 10 | Fishery reported average retained weight from fish tickets, or its average, and mean weights of legal males |
| Recruitment SD | $\sigma_{R}$ | 1.2 | High value |
| Natural mortality SD | $\sigma_{M}$ | 10.0 | High value (basically free parameter) |
| Directed fishery handling mortality |  | 0.2 | 2010 Crab SAFE |
| Groundfish trawl handling mortality |  | 0.8 | 2010 Crab SAFE |
| Groundfish fixed-gear handling mortality |  | 0.5 | 2010 Crab SAFE |

Table 25: The lower bound (LB), upper bound (UB), initial value, prior, and estimation phase for each estimated model parameter.

| Parameter | LB | Initial value | UB | Prior | Phase |
| :--- | ---: | ---: | ---: | :--- | ---: |
| Average recruitment $\log (R)$ | -7 | 10.0 | 20 | Uniform $(-7,20)$ | 1 |
| Stage-1 initial numbers $\log \left(n_{1}^{0}\right)$ | 5 | 14.5 | 20 | Uniform $(5,20)$ | 1 |
| Stage-2 initial numbers $\log \left(n_{2}^{0}\right)$ | 5 | 14.0 | 20 | Uniform $(5,20)$ | 1 |
| Stage-3 initial numbers $\log \left(n_{3}^{0}\right)$ | 5 | 13.5 | 20 | Uniform $(5,20)$ | 1 |
| ADF\&G pot survey catchability $q$ | 0 | 3.0 | 5 | Uniform $(0,5)$ | 1 |
| Stage-1 directed fishery selectivity 1978-2008 | 0 | 0.4 | 1 | Uniform $(0,1)$ | 3 |
| Stage-2 directed fishery selectivity 1978-2008 | 0 | 0.7 | 1 | Uniform $(0,1)$ | 3 |
| Stage-1 directed fishery selectivity 2009-2017 | 0 | 0.4 | 1 | Uniform $(0,1)$ | 3 |
| Stage-2 directed fishery selectivity 2009-2017 | 0 | 0.7 | 1 | Uniform $(0,1)$ | 3 |
| Stage-1 NMFS trawl survey selectivity | 0 | 0.4 | 1 | Uniform $(0,1)$ | 4 |
| Stage-2 NMFS trawl survey selectivity | 0 | 0.7 | 1 | Uniform $(0,1)$ | 4 |
| Stage-1 ADF\&G pot survey selectivity | 0 | 0.4 | 1 | Uniform $(0,1)$ | 4 |
| Stage-2 ADF\&G pot survey selectivity | 0 | 0.7 | 1 | Uniform $(0,1)$ | 4 |
| Natural mortality deviation during 1998 $\delta_{1998}^{M}$ | -3 | 0.0 | 3 | Normal $\left(0, \sigma_{M}^{2}\right)$ | 4 |
| Recruitment deviations $\delta_{y}^{R}$ | -7 | 0.0 | 7 | Normal $\left(0, \sigma_{R}^{2}\right)$ | 3 |
| Average directed fishery fishing mortality $\bar{F}^{\text {df }}$ | - | 0.2 | - | - | 1 |
| Average trawl bycatch fishing mortality $\bar{F}^{\mathrm{tb}}$ | - | 0.001 | - | - | 1 |
| Average fixed gear bycatch fishing mortality $\bar{F}^{\mathrm{fb}}$ | - | 0.001 | - | - | 1 |

# Norton Sound Red King Crab Stock Assessment for the fishing year 2018 

Toshihide Hamazaki ${ }^{1}$ and Jie Zheng ${ }^{2}$<br>Alaska Department of Fish and Game Commercial Fisheries Division<br>${ }^{1} 333$ Raspberry Rd., Anchorage, AK 99518-1565<br>Phone: 907-267-2158<br>Email: Toshihide.Hamazaki@alaska.gov<br>${ }^{2}$ P.O. Box 115526, Juneau, AK 99811-5526<br>Phone : 907-465-6102<br>Email : Jie.Zheng@alaska.gov

## Executive Summary

1. Stock. Red king crab, Paralithodes camtschaticus, in Norton Sound, Alaska.
2. Catches. This stock supports three important fisheries: summer commercial, winter commercial, and winter subsistence fisheries. Of those, the summer commercial fishery accounts for more than $90 \%$ of total harvest. The summer commercial fishery started in 1977, and catch peaked in the late 1970s with retained catch of over 2.9 million pounds. Since 1982, retained catches have been below 0.5 million pounds, averaging 0.275 million pounds, including several low years in the 1990s. Retained catches have increased to about 0.4 million pounds. Since mid-2010s, winter commercial fisheries catches has been increased greatly.
3. Stock Biomass. Following a peak in 1977, abundance of the stock collapsed to a historic low in 1982. Estimated mature male biomass (MMB) has shown an increasing trend since 1997, but is highly uncertain due, in part, to infrequent trawl (every 3 to 5 years) and limited winter pot surveys.
4. Recruitment. Model estimated recruitment was weak during the late 1970s and high during the early 1980s, with a slightly downward trend from 1983 to 1993. Estimated recruitment has been highly variable but on an increasing trend in recent years.
5. Management performance.

Status and catch specifications (million lb.)

| Year | MSST | Biomass <br> (MMB) | GHL | Retained <br> Commercial <br> Catch | Total <br> Retained <br> Catch | Retained <br> OFL | Retained <br> ABC |

6. Probability Density Function of the OFL, OFL profile, and mcmc estimates.

7. The basis for the ABC recommendation

For Tier 4 stocks, the default maximum ABC is based on $\mathrm{P}^{*}=49 \%$ that is essentially identical to the OFL. Accounting for uncertainties in assessment and model results, the SSC chose to use $90 \%$ OFL ( $10 \%$ Buffer) for the Norton Sound red king crab stock from 2011 to 2014. In 2015, the buffer was increased to $20 \%$ (ABC $=80 \%$ OFL).
8. A summary of the results of any rebuilding analyses.

N/A

## A. Summary of Major Changes in 2017

1. Changes to the management of the fishery:

Winter commercial GHL went into effect
2. Changes to the input data
a. Data update: 1977-2017 standardized commercial catch CPUE and CV. No changes in standardization methodology (NPFMC 2013).
b. Recalculation and standardization of 1996-2017ADFG trawl survey abundance.
i. Size class was changed from $\geq 74 \mathrm{~mm}$ to $\geq 64 \mathrm{~mm}$ to be consistent with the modeled size range
ii. Re-tow data were removed from abundance calculation, unless the first trawl failed.
iii. Estimates of abundance are based on core, tier 1, and tier 3 area only.
iv. Abundance of untrawled stations within the standard station was considered zero crabs. All untrawled stations were outer edge of standard stations (Appendix E).

Gray shaded area is standard stations.
3. Changes to the assessment methodology:

None
4. Changes to the assessment results.

None

## B. Response to SSC and CPT Comments

Crab Plan Team - January 17, 2017

- The CPT recommends breaking out natural mortality by size class for future model evaluation.

Authors' reply:
OFL calculation will change from
$O F L=\operatorname{Legal}_{-} B_{w}\left(1-e^{-\left(F_{\text {OFL }}+0.42 M\right)}-\left(1-e^{-0.42 M}\right)\left(\frac{1-p\left(1-e^{-\left(F_{\text {oFL }}+0.42 M\right)}\right)}{1-p\left(1-e^{-0.42 M}\right)}\right)\right)$
to
OFL $=\sum_{l}\left[\operatorname{Legal}_{-} B_{w, l}\left(1-e^{-\left(F_{\text {ofl, } l}+0.42 M_{l}\right)}-\left(1-e^{-0.42 M_{l}}\right)\left(\frac{1-p\left(1-e^{-\left(F_{\text {ofL }, l}+0.42 M_{l}\right)}\right)}{1-p\left(1-e^{-0.42 M_{l}}\right)}\right)\right)\right]$

- Assess which (2017 NOAA vs. ADFG survey) data inputs are most influential for the assessment.

Author reply: Model fit to ADFG trawl survey was better than NOAA trawl survey.

REC: Recruitment deviation
OBS: Summer commercial catch observer discards length composition
TAG: Tagging recovery data composition
Legal: Exploitable legal male crab

See Appendix C6-C13 for standard output figures. Estimates of parameters for each model are available by request.

The most influential data for the assessment is trawl survey abundance data that determined biomass. For length proportion data, model seems to resolve conflicts among various data, so that removing one data would increase fit to other data.

- Explore bycatch data to see if it is possible to determine the OFL as total catch.

Author reply:
Only discard length data were collected during the summer observer surveys. The author appreciates CPT's guidance for estimating the number and biomass of discarded crab from the length data.

SSC - January 30

- SSC suggests that the author examine available evidence for higher mortality rates at larger sizes and perhaps an alternative way to parameterizing higher mortality at age rather than a step change at the largest size class.

Author's reply:
Because NSRKC has only 8 size classes, we examined step change for each length classes in the following scenario:

1. One mortality for the last 2 length classes (default: $\mathrm{ms}=1$ )
2. Two separate mortalities for the last 2 length classes ( $\mathrm{ms}=2$ )
3. Three separate mortalities for the last 3 length classes ( $\mathrm{ms}=3$ )

The results showed that estimating mortality of the last 3 length classes seem to improve model fit, especially when fishery selectivity was converted from 1 parameter logistic to 2 parameters logistic model

| Scenario | M | ms | Fishery <br> Selectivity | Estimated <br> Mortality |

Crab Plan Team - Sept 20, 2017

- Include a graphic on where pot-pulls have been observed.

Author's reply
See Appendix D. The majority of observer surveys were conducted where the majority of crabs were harvested. This is expected. Observers can board on boats that are large enough that can harvest more crabs.
Bring forward default model, model 3, 4, 5 for the January 2018 assessment
Author's reply:
Base model along with alternative model $3,4,5$ were presented in the result section.

- Conduct likelihood profile on the M parameter

Author's reply:
See Appendix F.
Likelihood profile shows that $\mathrm{M}=0.26$ appeared to be the lowest. Among the likelihood components, influential factors were trawl and summer commercial length compositions.

- Include results for 2014-2016 pot survey data (but not for assessment) This was conducted only for the model 3.

SSC - Oct 02, 2017

- Same as CPT

## C. Introduction

1. Species: red king crab (Paralithodes camtschaticus) in Norton Sound, Alaska.
2. General Distribution: Norton Sound red king crab is one of the northernmost red king crab populations that can support a commercial fishery (Powell et al. 1983). It is distributed throughout Norton Sound with a westward limit of $167-168^{\circ} \mathrm{W}$. longitude, depths less than 30 m , and summer bottom temperatures above $4^{\circ} \mathrm{C}$. The Norton Sound red king crab management area consists of two units: Norton Sound Section (Q3) and Kotzebue Section (Q4) (Menard et al. 2011). The Norton Sound Section (Q3) consists of all waters in Registration Area Q north of the latitude of Cape Romanzof, east of the International Dateline, and south of $66^{\circ} \mathrm{N}$ latitude (Figure 1). The Kotzebue Section (Q4) lies immediately north of the Norton Sound Section and includes Kotzebue Sound. Commercial fisheries have not occurred regularly in the Kotzebue Section. This report deals with the Norton Sound Section of the Norton Sound red king crab management area.
3. Evidence of stock structure: Thus far, no studies have investigated possible stock separation within the putative Norton Sound red king crab stock.
4. Life history characteristics relevant to management: One of the unique life-history traits of Norton Sound red king crab is that they spend their entire lives in shallow water since Norton Sound is generally less than 40 m in depth. Distribution and migration patterns of Norton Sound red king crab have not been well studied. Based on the 1976-2006 trawl surveys, red
king crab in Norton Sound are found in areas with a mean depth range of $19 \pm 6$ (SD) m and bottom temperatures of $7.4 \pm 2.5(\mathrm{SD})^{\circ} \mathrm{C}$ during summer. Norton Sound red king crab are consistently abundant offshore of Nome.

Norton Sound red king crab migrate between deeper offshore and inshore shallow waters. Timing of the inshore mating migration is unknown, but is assumed to be during late fall to winter (Powell et al. 1983). Offshore migration occurs in late May - July (Jennifer Bell, ADF\&G, personal communication). The results from a study funded by North Pacific Research Board (NPRB) during 2012-2014 suggest that older/large crab (> 104mm CL) stay offshore in winter, based on findings that large crab are not found nearshore during spring offshore migration periods (Jennifer Bell, ADF\&G, personal communication). Timing of molting is unknown but likely occurs in late August - September, based on increase catches of newly-molted crab late in the fishing season (August- September) (Joyce Soong, ADF\&G personal communication) and evaluation of molting hormone profiles in the hemolymph (Jennifer Bell, ADF\&G, personal communication). Recent observations also indicate that mating may be biennial (Robert Foy, NOAA, personal communication). Trawl surveys show that crab distribution is dynamic with recent surveys showing high abundance on the southeast side of Norton Sound, offshore of Stebbins and Saint Michael.
5. Brief management history: Norton Sound red king crab fisheries consist of commercial and subsistence fisheries. The commercial red king crab fishery started in 1977 and occurs in summer (June - August) and winter (December - May). The majority of red king crab harvest occurs offshore during the summer commercial fishery, whereas the winter commercial and subsistence fisheries occur nearshore through ice.

## Summer Commercial Fishery

A large-vessel summer commercial crab fishery started in 1977 in the Norton Sound Section (Table 1) and continued from 1977 through 1990. No summer commercial fishery occurred in 1991 because there were no staff to manage the fishery. In March 1993, the Alaska Board of Fisheries (BOF) limited participation in the fishery to small boats. Then on June 27, 1994, a super-exclusive designation went into effect for the fishery. This designation stated that a vessel registered for the Norton Sound crab fishery may not be used to take king crabs in any other registration areas during that registration year. A vessel moratorium was put into place before the 1996 season. This was intended to precede a license limitation program. In 1998, Community Development Quota (CDQ) groups were allocated a portion of the summer harvest; however, no CDQ harvest occurred until the 2000 season. On January 1, 2000 the North Pacific License Limitation Program (LLP) went into effect for the Norton Sound crab fishery. The program dictates that a vessel which exceeds 32 feet in length overall must hold a valid crab license issued under the LLP by the National Marine Fisheries Service. Changes in regulations and the location of buyers resulted in eastward movement of the harvest distribution in Norton Sound in the mid-1990s. In Norton Sound, a legal crab is defined as $\geq$ 4-3/4 inch carapace width (CW, Menard et al. 2011), which is approximately equivalent to $\geq$ 104 mm carapace length mm CL. Since 2005, commercial buyers (Norton Sound Economic Development Corporation) started accepting only legal crab of $\geq 5$ inch CW. This may have increased discards; however, because discards have not been monitored until 2012, impact of this change on discards is unknown. This issue was also examined in assessment model
selection, which showed no difference in estimates of selectivity functions before and after 2005 (NPFMC 2016).

Portions of Norton Sound area are closed to commercial fishing for red king crab. Since the beginning of the commercial fisheries in 1977, waters approximately 5-10 miles offshore of southern Seward Peninsula from Port Clarence to St. Michael have been closed to protect crab nursery grounds during the summer commercial crab fishery (Figure 2). The spatial extent of closed waters has varied historically.

## CDQ Fishery

The Norton Sound and Lower Yukon CDQ groups divide the CDQ allocation. Only fishers designated by the Norton Sound and Lower Yukon CDQ groups are allowed to participate in this portion of the king crab fishery. Fishers are required to have a CDQ fishing permit from the Commercial Fisheries Entry Commission (CFEC) and register their vessel with the Alaska Department of Fish and Game (ADF\&G) before begin fishing. Fishers operate under the authority of each CDQ group who decides how their crab quota is to be harvested. During the March 2002 BOF meeting, new regulations for the CDQ crab fishery were adopted that affected; closed-water boundaries were relaxed in eastern Norton Sound and waters west of Sledge Island. In March 2008, the BOF changed the start date of the Norton Sound open-access portion of the fishery to be opened by emergency order as early as June 15. The CDQ fishery may open at any time (as soon as ice is out), by emergency order. CDQ harvest share is $7.5 \%$ of total projected harvest.

## Winter Commercial Fishery

The winter commercial crab fishery is a small fishery using hand lines and pots through the nearshore ice. On average 10 permit holders harvested 2,500 crabs during 1978-2009. From 2007 to 2015 the winter commercial catch increased from 3,000 crabs to over 40,000 (Table 2). In 2015 winter commercial catch reached $20 \%$ of total crab catch. The BOF responded in May 2015 by amending regulations to allocate 8\% of the total commercial guideline harvest level (GHL) to the winter commercial fishery, which became in effect since 2017 season. The winter red king crab commercial fishing season was also set from January 15 to April 30, unless changed by emergency order. The new regulation became in effect since the 2016 season.

## Subsistence Fishery

While the winter subsistence fishery has a long history, harvest information is available only since the 1977/78 season. The majority of the subsistence crab fishery harvest occurs using hand lines and pots through nearshore ice. Average annual winter subsistence harvest was 5,400 crab (1977-2010). Subsistence harvesters need to obtain a permit before fishing and record daily effort and catch. There are no size or sex specific harvest limits; however, the majority of retained catches are males of near legal size. The subsistence fishery catch is influenced not only by crab abundance, but also by changes in distribution, changes in gear (e.g., more use of pots instead of hand lines since 1980s), and ice conditions (e.g., reduced catch due to unstable ice conditions: 1987-88, 1988-89, 1992-93, 2000-01, 2003-04, 2004-05, and 2006-07).

The summer subsistence crab fishery harvest has been monitored since 2004 with an average harvest of 712 crab per year. Since this harvest is very small, the summer subsistence fishery was not included in the assessment model.
6. Brief description of the annual ADF\&G harvest strategy

Since 1997 Norton Sound red king crab has been managed based on a guideline harvest level (GHL). From 1999 to 2011 the GHL for the summer commercial fishery was determined by a prediction model and the model estimated predicted biomass: (1) $0 \%$ harvest rate of legal crab when estimated legal biomass $<1.5$ million lb ; $(2) \leq 5 \%$ of legal male abundance when the estimated legal biomass falls within the range 1.5-2.5 million lb; and ( 3 ) $\leq 10 \%$ of legal male when estimated legal biomass $>2.5$ million lb .

In 2012 a revised GHL for the summer commercial fishery was implemented: (1) $0 \%$ harvest rate of legal crab when estimated legal biomass < 1.25 million lb ; ( 2 ) $\leq 7 \%$ of legal male abundance when the estimated legal biomass falls within the range $1.25-2.0$ million lb ; $(3) \leq$ $13 \%$ of legal male abundance when the estimated legal biomass falls within the range 2.0-3.0 million lb; and (3) $\leq 15 \%$ of legal male biomass when estimated legal biomass $>3.0$ million lb.

In 2015 the Alaska Board of Fisheries passed the following regulations regarding winter commercial fisheries:

1. Revised GHL to include summer and winter commercial fisheries.
2. Set guideline harvest level for winter commercial fishery $\left(\mathrm{GHL}_{\mathrm{w}}\right)$ at $8 \%$ of the total GHL
3. Dates of the winter red king crab commercial fishing season are from January 15 to April 30.

| Year | Notable historical management changes |
| :--- | :--- |
| 1976 | The abundance survey started |
| 1977 | Large vessel commercial fisheries began |
| 1991 | Fishery closed due to staff constraints |
| 1994 | Super exclusive designation went into effect. The end of large vessel commercial fishery <br> operation. The majority of commercial fishery subsequently shifted to east of $164^{\circ}$ W longitude. |
| 1998 | Community Development Quota (CDQ) allocation went into effect |
| 1999 | Guideline Harvest Level (GHL) went into effect |
| 2000 | North Pacific License Limitation Program (LLP) went into effect. |
| 2002 | Change in closed water boundaries (Figure 2) |
| 2005 | Commercially accepted legal crab size changed from $\geq 4-3 / 4$ inch CW to $\geq 5$ inch CW |
| 2006 | The Statistical area Q3 section expanded (Figure 1 ) |

7. Summary of the history of the $B_{\text {MSY }}$.

NSRKC is a Tier 4 crab stock. Direct estimation of the $B_{\text {MSy }}$ is not possible. The $B_{\text {msy }}$ proxy is calculated as mean model estimated mature male biomass (MMB) from 1980 to present. Choice of this period was based on a hypothesized shift in stock productivity a due to a climatic regime shift indexed by the Pacific Decadal Oscillation (PDO) in 1976-77. Stock status of the NSRKC was Tier 4a until 2013. In 2014 the stock fell to Tier 4b, but came back to Tier 4a for the 2015-2016 seasons.

## D. Data

1. Summary of new information:

Winter commercial and subsistence fishery:
Winter commercial fishery catch in 2017 was 26,008 crab (77,843 lb.), declined slightly from 2016. Subsistence retained crab catch was 6,039 and unretained was 1,146 or $16 \%$ of total catch (Table 2).

Summer commercial fishery:
The summer commercial fishery opened on June 26 and closed on July 25. Total of 135,322 crab ( $411,736 \mathrm{lb}$.) were harvested (Table 1).

Total retained harvest for 2017 season was 167,369 crab ( $501,637 \mathrm{lb}$.) and did not exceed the 2017 ABC of 0.54 million lb.

Summer Trawl abundance survey ADFG (7/28-8/08), and NOAA (8/18-829).
Abundance estimated by ADFG survey was 1762.1 (x 1000) crab with CV 0.22 , and that by NOAA survey was 1035.8 (x 1000) crab with CV 0.40 (Table 3). It should be noted that total estimation arear and survey station density differ between the two trawl surveys. ADFG survey is based on 10 nm grids whereas NOAA survey is based on 20 nm grids.

2017 ADFG trawl survey coverage (Yellow shade) and NOAA Trawl survey coverage where abundance estimates were made (Red hashed line)
2. Available survey, catch, and tagging data

|  | Years | Data Types | Tables |
| :--- | :--- | :--- | :--- |

1: Index of abundance data: N: Abundance, H: Harvest, CPUE: Catch cpue
2: Length data available
3: Data were not used for the assessment model because of short term data.
4: Different colors indicate changes in fishery characteristics or survey methodologies.

## Catches in other fisheries

In Norton Sound, no other crab, groundfish, or shellfish fisheries exist.

|  | Fishery | Data availability |
| :--- | :--- | :---: |
| Bycatch in other crab <br> fisheries | Does not exist | NA |
| Bycatch in groundfish pot | Does not exist | NA |
| Bycatch in groundfish trawl | Does not exist | NA |
| Bycatch in the scallop fishery | Does not exist | NA |

3. Other miscellaneous data:

Satellite tag migration tracking (NOAA 2016)
Spring offshore migration distance and direction (2013-2015)
Monthly blood hormone level (indication of molting timing) (2014-2015)
Data aggregated:
Proportion of legal size crab, estimated from trawl survey and observer data. (Table 11)
Data estimated outside the model:
Summer commercial catch standardized CPUE (Table 1, Appendix A2)

## E. Analytic Approach

## 1. History of the modeling approach.

The Norton Sound red king crab stock was assessed using a length-based synthesis model (Zheng et al. 1998). Since adoption of the model, the major challenge is a conflict between model projection and data, specifically the model projects higher abundanceproportion of large size class (> 123mm CL) of crab than observed. This problem was further exasperated when natural mortality $M$ was set to 0.18 from previous $M=0.3$ in 2011 (NPFMC 2011). This issue has been resolved by assuming (3-4 times) higher $M$ for the length crabs (i.e., $M=1.8$ for length classes $\leq 123 \mathrm{~mm}$, and higher $M$ for $>123 \mathrm{~mm}$ ) (NPFMC 2012, 2013, 2014, 2015, 2016, 2017). Alternative assumptions have been explored, such as changing molting probability (i.e., crab matured quicker or delayed maturation), higher natural mortality, and dorm shaped selectivity (i.e., large crab are not caught, or moved out of fishery/survey grounds). However, those alternative assumptions did not produce better model fits. Model estimated length specific molting probability was similar to inverse logistic curve, and did not improve model fit (NPFMC 2016). Assuming constant across all length classes resulted in higher $M$ (0.3-0.45) (NPFMC 2013, 2017). Assuming dome shaped selectivity resulted in large (>123mm CL) of crabs consisting of $50 \%$ of MMB move out of Norton Sound fishery and survey area and never been seen. For the 2018 gradual increase of $M$ across length classes was assessed.

Historical Model configuration progression:

2011 (NPFMC 2011)

1. $M=0.18$
2. $M$ of the last length class $=0.288$
3. Include summer commercial discards mortality $=0.2$
4. Weight of fishing effort $=20$,
5. The maximum effective sample size for commercial catch and winter surveys $=100$,

2012 (NPFMC 2012)

1. $M$ of the last length class $=3.6 \times M$
2. The maximum effective sample size for commercial catch and winter surveys $=50$,
3. Weight of fishing effort $=50$.

2013 (NPFMC 2013)

1. Eliminate likelihood for fishing effort and use standardized commercial catch cpue likelihood. weight $=1.0$
2. Eliminate summer pot survey data from likelihood
3. Estimate survey $q$ of 1976 -1991 NMFS survey with maximum of 1.0
4. The maximum input sample size for commercial catch and winter surveys $=10$.
5. The maximum input sample size for trawl survey $=20$.

2014 (NPFMC 2014)

1. Modify functional form of selectivity and molting probability to improve parameter estimates (2 parameter logistic to 1 parameter logistic)
2. Include additional variance for the standardized cpue.
3. Include winter pot survey cpue (But was removed from the final model due to lack of fit)
4. Estimate growth transition matrix from tagged recovery data.

## 2015 (NPFMC 2015)

1. Change winter pot survey selectivity is to inverse logistic, estimating selectivity of the smallest length group independently
2. Reduce weight of tag-recovery: $\mathrm{W}=0.5$
3. Model parsimony: one trawl survey selectivity and one commercial pot selectivity
4. Change assessment model periods from July 01 - June 30 to Feb 01 - Jam 31.
5. OFL winter and summer fishery combined.

2016 (NPFMC 2016)

1. Length range extended from $74 \mathrm{~mm}-124 \mathrm{~mm}$ above (6 length classes) to $64 \mathrm{~mm}-$ 134mm above (8 length classes).
2. Estimate multiplier for the largest (> 123mm) length classes.

2017 (NPFMC 2017)

1. Change molting probability function form 1 to 2 parameter logistic. Assume molting probability not reaching 1 for the smallest length class.
2. OFL account for winter and summer fishery separately. Account for natural mortality between the two fishery periods (5 months)

## 2. Model Description

a. Description of overall modeling approach:

The model is a male-only size structured model that combines multiple sources of survey, catch, and mark-recovery data using a maximum likelihood approach to estimate abundance, recruitment, catchability of the commercial pot gear, and parameters for selectivity and molting probabilities (See Appendix A for full model description).

Unlike other crab assessment models, NSRK modeling year is starts from February $1^{\text {st }}$ to January $31^{\text {st }}$ of the following year. This schedule was selected because Norton Sound winter crab fisheries can start when Norton Sound ice become thick enough to operate fishery safely, which can be as earliest as mid-late January.
b-f. See Appendix A.
g. Critical assumptions of the model:
i. Male crab mature at CL length 94 mm .

Size at maturity of NSRKC (CL 94 mm ) was determined by adjusting that of BBRKC
(CL 120mm) reflect the slower growth and smaller size of NSRKC.
ii. Molting occurs in the fall after the summer fishery
iii. Instantaneous natural mortality $M$ is 0.18 for all length classes, except for the last length group (> 123mm).
iv. Trawl survey selectivity is a logistic function with 1.0 for length classes 5-6. . Selectivity is constant over time.
v. Winter pot survey selectivity is a dome shaped function: Reverse logistic function of 1.0 for length class CL 84 mm , and model estimate for CL < 84mm length classes. Selectivity is constant over time.
This assumption is based on the fact that a low proportion of large crab are caught in the nearshore area where winter surveys occur. Causes of this pattern may be that (1) large crab do not migrate into nearshore waters in winter or (2) large crab are fished out by winter fisheries where the survey occurs (i.e., local depletion). Recent studies suggest that the first explanation is more likely than second (Jennifer Bell, ADFG, personal communication).
vi. Summer commercial fisheries selectivity is an asymptotic logistic function of 1.0 at the length class CL 134 mm . While the fishery changed greatly between the periods (1977-1992 and 1993-present) in terms of fishing vessel composition and pot configuration, the selectivity of each period was assumed to be identical. Model fits of separating and combining the two periods were examined in 2015, and showed no difference between the two models (NPFMC 2015). For model parsimony, the two were combined.
vii. Summer trawl survey selectivity is an asymptotic logistic function of 1.0 at the length of CL 124mm. While the survey changed greatly between NOAA (19761991) and ADF\&G (1996-present) in terms of survey vessel and trawl net structure, selectivity of both periods was assumed to be identical. Model fits separating and combining the two surveys were examined in 2015. No differences between the two models were observed (NPFMC 2015) and for model parsimony the two were combined.
viii. Winter commercial and subsistence fishery selectivity and length-shell conditions are the same as those of the winter pot survey. All winter commercial and subsistence harvests occur February $1^{\text {st }}$.

Winter commercial king crab pots can be any dimension (5AAC 34.925(d)). No length composition data exists for crab harvested in the winter commercial or subsistence fisheries. However, because commercial fishers are also subsistence fishers, it is reasonable to assume that the commercial fishers used crab pots that they use for subsistence harvest, and hence both fisheries have the same selectivity.
ix. Growth increments are a function of length, are constant over time, estimated from tag recovery data.
x. Molting probability is an inverse logistic function of length for males.
xi. A summer fishing season for the directed fishery is short. All summer commercial harvests occur July $1^{\text {st }}$.
xii. Discards handling mortality rate for all fisheries is 20\%.

No empirical estimate is available.
xiii. Annual retained catch is measured without error.
xiv. All legal size crab ( $\geq 4-3 / 4$ inch CW) are retained, and sublegal size crab or commercially unacceptable size crab (< 5 inch CW, since 2005) are discarded.

Since 2005, buyers announced that only legal crab with $\geq 5$ inch CW are acceptable for purchase. Since samples are taken at a commercial dock, it was anticipated that this change would lower the proportion of legal crab. However, the model was not sensitive to this change (NPFMC 2013, 2017).
xv. Length compositions have a multinomial error structure and abundance has a lognormal error structure.
h. Changes of assumptions since last assessment:

None.

## 3. Model Selection and Evaluation

a. Description of alternative model configurations.

Following CPT and SSC’s recommendation in fall 2017, we brought base model (2017 assessment model), model 3, 4, and 5 . Also, we examined potential impacts of spring survey data (model 6).

## List of model scenarios explored:

| Scenario | I | ms | Fishery <br> Selectivity | Estimated <br> $M$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0.18 | 1 | 1 p | 0.579 |
| 3 | 0.18 | 1 | 2 p | 0.595 |
| 4 | 0.18 | 2 | 2 p | $0.576,0.634$ |
| 5 | 0.18 | 3 | 2 p | $0.340,0.547,0.584$ |
| 6 | 0.18 | 1 | 2 p | 0.592 |

$\mathrm{ms}=1$ : Estimate one mortality for the last 2 length classes ( $124 \mathrm{~mm}, 134 \mathrm{~mm}$ )
$\mathrm{ms}=2$ : Estimate two separate mortalities for the last 2 length classes ( $124 \mathrm{~mm}, 134 \mathrm{~mm}$ )
$\mathrm{ms}=3$ : Estimate three separate mortalities for the last 3 length classes ( $114 \mathrm{~mm}, 124 \mathrm{~mm}, 134 \mathrm{~mm}$ )
Fishery selectivity model function
1 parameter logistic selectivity model

$$
S_{l}=\frac{1}{1+e^{\left(\phi\left(L_{\max }-L\right)+\ln (1 / 0.999-1)\right)}}
$$

2 parameters logistic selectivity model

$$
S_{l}=\frac{1}{1+e^{-\alpha(L-\beta)}}
$$

b. Evaluation of negative log-likelihood alternative models results:

| Model | Model <br> 0 | Model <br> 3 | Model <br> 4 | Model <br> 5 | Model <br> 6 |

TSA: Trawl Survey Abundance

St. CPUE: Summer commercial catch standardized CPUE
TLP: Trawl survey length composition:
WLP: Winter pot survey length composition
CLP: Summer commercial catch length composition
REC: Recruitment deviation
OBS: Summer commercial catch observer discards length composition
TAG: Tagging recovery data composition
Legal: Exploitable legal male crab
See Appendix C1-C5 for standard output figures and estimated parameters.
a. Search for balance:

Changing to 2 parameters logistic model and stepwise length specific mortality decreased negative log-likelihood and improved model fit. Relative gain of model improvement was the largest from model 0 to model 3 (i.e., changing the shape of commercial pot selectivity). The majority of model fit was attributed to likelihood of Trawl survey and tag recovery length proportion (cf. Appendix C1, C2 Figures 11, 12, 13). Simultaneously, it should be noted that extent of reduction depends upon assumed input sample size. Subdividing natural mortality and increasing one more parameter size (from model 3 to 4 ) did not change model fit. Though some improvement was seen from model 4 to 5 , it was argued that assuming natural mortality increase of crab size 114-123mm would be biologically unreasonable (CPT Sept 2017). Changing of fishery selectivity or subdividing mortality did not change MMB projections, but reduced legal crab biomass catchable to commercial fishery. This is because the shape of the selectivity became steeper (cf. Appendix C1, C2 Figure 3).
While there was an improvement in fit from model 0 to model 3, the improvement in fit was not to the fishery length composition data as would be expected, but instead to other data sets unrelated to the fishery, such as the tagging data and the survey size composition. In addition, the estimated selectivity pattern was gradually inclining curve that continued to increase at sizes above the legal limit, a pattern which the CPT found difficult to rationalize. This suggests that the model uses more flexible two-parameter selectivity curve to account for some other unmodeled process, and therefore should not be considered a model improvement.

Based on the above arguments the Model 0 was selected for assessment of 2018

## 4. Results

1. List of effective sample sizes and weighting factors (Figure 4)
"Implied" effective sample sizes were calculated as

$$
n=\sum_{l} \hat{P}_{y, l}\left(1-\hat{P}_{y, l}\right) / \sum_{l}\left(P_{y, l}-\hat{P}_{y, l}\right)^{2}
$$

Where $P_{y, l}$ and $\hat{P}_{y, l}$ are observed and estimated length compositions in year $y$ and length group $l$, respectively. Estimated effective sample sizes vary greatly over time.

Maximum input sample sizes for length proportions: The maximum input sample size was arbitrary selected for better fit (NPFMC 2013)

| Survey data | Sample size |
| :--- | :--- |
| Summer commercial, winter pot, <br> and summer observer | minimum of $0.1 \times$ actual sample size or 10 |
| Summer trawl | minimum of $0.5 \times$ actual sample size or 20 |
| Tag recovery | $0.5 \times$ actual sample size |

Weighting factor
Recruitment SD 0.5
2. Tables of estimates.
a. Model parameter estimates (Tables 10, 11, 12, 13).
b. Abundance and biomass time series (Table 13)
c. Recruitment time series (Table 13).
d. Time series of catch/biomass (Tables 13 and 14)
3. Graphs of estimates.
a. Molting probability and trawl/pot selectivity (Figure 5)
b. Trawl survey and model estimated trawl survey abundance (Figure 6)
c. Estimated male abundances (recruits, legal, and total) (Figure 7)
d. Estimated mature male biomass (Figure 8)
e. Time series of standardized cpue for the summer commercial fishery (Figure 9).
f. Time series of catch and estimated harvest rate (Figure 10).
4. Evaluation of the fit to the data.
a. Fits to observed and model predicted catches.

Not applicable. Catch is assumed to be measured without error; however fits of cpue are available (Figures 9, 11).
b. Model fits to survey numbers (Figures 6, 11).

All model estimated abundances of total crab were within the $95 \%$ confidence interval of the survey observed abundance, except for 1976 and 1979, where model estimates were higher than the observed abundances.
c. Fits of catch proportions by lengths (Figures 12, 13).
d. Model fits to catch and survey proportions by length (Figures 12, 14, 15, 16).
e. Marginal distribution for the fits to the composition data
f. Plots of implied versus input effective sample sizes and time-series of implied effective sample size (Figure 4).
g. Tables of RMSEs for the indices:

Trawl survey:
Summer commercial standardized CPUE: (Table 1)
h. QQ plots and histograms of residuals (Figure 11).
5. Retrospective analyses (Figure 17).

Mohn's rho was 0.213 from 2007-2017. Mohn's rho suggests that retrospective projections are more likely to overestimate abundance. However, Mohns' rho has NO statistical range criteria of whether an assessment model is deemed acceptable/ unacceptable.
6. Uncertainty and sensitivity analyses.

See Sections 2 and 5.

## a) Calculation of the OFL

1. Specification of the Tier level and stock status.

The Norton Sound red king crab stock is placed in Tier 4. It is not possible to estimate the spawner-recruit relationship, but some abundance and harvest estimates are available to build a computer simulation model that captures the essential population dynamics. Tier 4 stocks are assumed to have reliable estimates of current survey biomass and instantaneous $M$; however, the estimates for the Norton Sound red king crab stock are uncertain.
Tier 4 level and the OFL are determined by the $F_{M S Y}$ proxy, $B_{M S Y}$ proxy, and estimated legal male abundance and biomass:

| level | Criteria | $F_{\text {OFL }}$ |
| :---: | :---: | :---: |
| a | $B / B_{\text {MSY }}{ }^{\text {prax }}$ $>1$ | $F_{\text {OFL }}=\gamma M$ |
| b |  | $F_{\text {OFL }}=\gamma M_{l}\left(B / B_{M S Y \text { prox }}-\alpha\right) /(1-\alpha)$ |
| c | $B / B_{\text {MSY }}{ }^{\text {prox }}$ $\leq \beta$ | $F_{\text {OFL }}=$ bycatch mortality \& directed fishery F $=0$ |

where $B$ is a mature male biomass (MMB), $B_{M S Y}$ proxy is average mature male biomass over a specified time period, $M=0.18, \gamma=1, \alpha=0.1$, and $\beta=0.25$

For Norton Sound red king crab, MMB is defined as the biomass of males $>94 \mathrm{~mm}$ CL on February 01 (Appendix A). BMSY proxy is
$B_{\text {MSY }}$ proxy = average model estimated MMB from 1980-2018
Predicted mature male biomass in 2018 on February 01 is:

Mature male biomass: 4.08 (SD 0.54) million lb.
Estimated $B_{M S Y}$ proxy is:
4.82 million lb.

Since projected MMB is less than $B_{M S Y}$ proxy, Norton Sound red king crab stock status is Tier 4b
2. Calculation of OFL.

OFL for the Norton Sound Red King Crab is retained ( $O F L_{r}$ ) of legal sized crab biomass, Legal_B.
Legal_B is a biomass of legal sized crab subject to fisheries and is calculated as: Projected abundance by length class on Feb $01\left(N_{w, l}+O_{w, l}\right) \times$ summer fishing selectivity by length class $\left(S_{s, l}\right) \times$ Proportion of legal crab per length class $\left(P_{l g, l}\right) \times$ average lb per length class ( $w m_{l}$ ).
For the Norton Sound red king crab assessment, Legal_B was defined as winter biomass catchable to summer commercial pot fishery gear Legal_ $B_{w}$, as

$$
\text { Legal_ }_{-} B_{w}=\sum_{l}\left(N_{w, l,}+O_{w, l}\right) S_{s, l} P_{l g, l} w m_{l}
$$

The Norton Sound red king crab fishery consists of two distinct fisheries: winter and summer. The two fisheries are discontinuous with 5 months between the two fisheries during which natural mortalities occur. To incorporate this fishery, the CPT in 2016 recommended the following formula:

$$
\begin{aligned}
& \text { Legal_ }_{1}=\text { Legal }_{-} B_{w}\left(1-\exp \left(-x \cdot F_{\text {OFL }}\right)\right) e^{-0.42 M} \\
& \text { OFL }_{r}=\left(1-\exp \left(-(1-x) \cdot F_{\text {OFL }}\right)\right) \text { Legal }_{\_} B_{s}
\end{aligned}
$$

And $\quad p=\frac{\text { Legal }_{-} B_{w}\left(1-\exp \left(-x \cdot F_{O F L}\right)\right)}{O F L_{r}}$
Where $p$ is a specific proportion of winter crab harvest to total (winter + summer) harvest.
Solving $x$ of the above, a revised retained OFL is

$$
O F L_{r}=\text { Legal }_{-} B_{w}\left(1-e^{-\left(F_{\text {OFI }}+0.42 M\right)}-\left(1-e^{-0.42 M}\right)\left(\frac{1-p \cdot\left(1-e^{-\left(F_{\text {OFL }}+0.42 M\right)}\right)}{1-p \cdot\left(1-e^{-0.42 M}\right)}\right)\right)
$$

Accounting for difference in length specific natural mortality

$$
O F L_{r}=\sum_{l}\left[\operatorname{Legal}_{-} B_{w, l}\left(1-e^{-\left(F_{\text {oF, }, l}+0.42 M_{l}\right)}-\left(1-e^{-0.42 M_{l}}\right)\left(\frac{1-p \cdot\left(1-e^{-\left(F_{\text {ofl }, l}+0.42 M_{l}\right)}\right)}{1-p \cdot\left(1-e^{-0.42 M_{l}}\right)}\right)\right)\right]
$$

For calculation of the $\mathrm{OFL}_{r}$ 2018, we specified $p=0.16, M_{l}=0.18$ for all length classes for calculation of $F_{\text {OFL }}$, and $M_{l}=0.58$ for length classes greater than 123 mm .

Legal male biomass catchable to fishery (Feb 01): 3.549 million lb $\mathrm{OFL}_{\mathrm{r}}=0.43$ million lb. or 0.20 kMT

## b) Calculation of the ABC

1. Specification of the probability distribution of the OFL.

Retained ABC for legal male crab is $80 \%$ of OFL
$\mathrm{ABC}=0.35$ million lb or 0.16 kMT

## c) Rebuilding Analyses

Not applicable

## d) Data Gaps and Research Priorities

The major data gap is the fate of crab greater than 123 mm . Estimates of discard is needed for calculation of total OFL.

## Acknowledgments

We thank all CPT members for all review of the assessment model and suggestions for improvements and diagnoses. We also thank Dr. Shareef Siddeek for critical review of draft.

a Prior to 1985 the winter commercial fishery occurred from January 1 - April 30. As of March 1985, fishing may occur from November 15 - May 15.
b The winter subsistence fishery occurs during months of two calendar years (as early as December, through May).
c The number of crab actually caught; some may have been returned.
d The number of crab retained is the number of crab caught and kept.
f Confidentiality was waived by the fishers.
h Prior to 2005, permits were only given out of the Nome ADF\&G office. Starting with the 2004-5 season, permits were given out in
Elim, Golovin, Shaktoolik, and White Mountain.

Table 3. Summary of triennial trawl survey Norton Sound male red king crab abundance estimates (CL $\geq 64 \mathrm{~mm}$ ). Trawl survey abundance estimate is based on $10 \times 10 \mathrm{~nm}^{2}$ grid, except for 2010 and 2017 $\left(20 \times 20 \mathrm{~nm}^{2}\right)$. Bold typed data are used for the assessment model.

| Year | Dates | Survey <br> Agency | Survey method | Survey coverage |  |  | $\begin{gathered} \text { Abundance } \\ \geq 74 \mathrm{~mm}(1982-1991) \\ \geq 64 \mathrm{~mm}(1996-2007) \end{gathered}$ |  |

Table 11. Summary of initial input parameter values and bounds for a length-based population model of Norton Sound red king crab. Parameters with " $\log _{\_}$" indicate $\log$ scaled parameters.

| Parameter | Parameter description | Equation Number in Appendix A | Lower | Upper |
| :---: | :---: | :---: | :---: | :---: |
| $\log _{\text {_ }} \mathrm{q}_{1,2}$ | Commercial fishery catchability (1977-92, 19932017) | (22) | -20.5 | 20 |
| $\log _{-} \mathrm{N}_{76}$ | Initial abundance | (1) | 2.0 | 15.0 |
| $\mathrm{R}_{0}$ | Mean Recruit | (13) | 2.0 | 12.0 |
| $\log _{\_} \sigma_{R}{ }^{2}$ | Recruit standard deviation | (13) | -40.0 | 40.0 |
| $\mathrm{a}_{1-7}$ | Intimal length proportion | (2) | 0 | 10.0 |
| $\mathrm{r}_{1}$ | Proportion of length class 1 for recruit | (14) | 0 | 10.0 |
| $\log _{-} \alpha$ | Inverse logistic molting parameter | (15) | -5.0 | -1.0 |
| $\log _{\_} \beta$ | Inverse logistic molting parameter | (15) | 1.0 | 5.5 |
| $\log _{-} \phi_{\text {st1 }}$ | Logistic trawl selectivity parameter | (16) | -5.0 | 1.0 |
| $\log _{-} \phi_{w 1}$ | Inverse logistic winter pot selectivity parameter | (18) | -5.0 | 1.0 |
| $\log _{-} \phi_{w 2}$ | Inverse logistic winter pot selectivity parameter | (18) | 0.0 | 6.0 |
| $\mathrm{SW}_{1,2}$ | Winter pot selectivity of length class 1,2 | (18) | 0.1 | 1.0 |
| $\log _{-} \phi_{l}$ | Logistic commercial catch selectivity parameter | (17) | -5.0 | 1.0 |
| $\log _{-} \phi_{2}$ | Logistic commercial catch selectivity parameter | (17) | 0.0 | 6.0 |
| $w_{t}^{2}$ | Additional variance for standard CPUE | (31) | 0.0 | 6.0 |
| ms | Natural mortality multipliers |  | 0.5 | 5.0 |
| q | Survey q for NMFS trawl 1976-91 | (31) | 0.1 | 1.0 |
| $\sigma$ | Growth transition sigma | (19) | 0.0 | 30.0 |
| $\beta_{1}$ | Growth transition mean | (19) | 0.0 | 20.0 |
| $\beta_{2}$ | Growth transition increment | (19) | 0.0 | 20.0 |

Table 12. Summary of parameter estimates and standard deviations of Norton Sound red king crab. (Base Model 0)

| name | Estimate | std.dev |

## Appendix A. Description of the Norton Sound Red King Crab Model

## a. Model description.

The model is an extension of the length-based model developed by Zheng et al. (1998) for Norton Sound red king crab. The model has 8 male length classes with model parameters estimated by the maximum likelihood method. The model estimates abundances of crab with CL $\geq 64 \mathrm{~mm}$ and with $10-\mathrm{mm}$ length intervals ( 8 length classes, $\geq 134 \mathrm{~mm}$ ) because few crab measuring less than 64 mm CL were caught during surveys or fisheries and there were relatively small sample sizes for trawl and winter pot surveys. The model treats newshell and oldshell male crab separately but assumes they have the same molting probability and natural mortality.

Norton Sound Red King Crab Modeling Scheme

Timeline of calendar events and crab modeling events:

- Model year starts February $1^{\text {st }}$ to January $31^{\text {st }}$ of the following year.
- All winter fishery harvest occurs on February $1^{\text {st }}$
- Molting and recruitment occur on July $1^{\text {st }}$
- Initial Population Date: February $1^{\text {st }} 1976$

Abundance of the initial pre-fishery population was assumed to consist of newshell crab to reduce the number of parameters, and estimated as

$$
\begin{equation*}
N_{l, 1}=p_{l} e^{\log _{-} N_{76}} \tag{1}
\end{equation*}
$$

where, length proportion of the first year $\left(p_{l}\right)$ was calculated as

$$
\begin{align*}
& p_{l}=\frac{\exp \left(a_{l}\right)}{1+\sum_{l=1}^{n-1} \exp \left(a_{l}\right)} \text { for } l=1, . ., n-1 \\
& p_{n}=1-\frac{\sum_{l=1}^{n-1} \exp \left(a_{l}\right)}{1+\sum_{l=1}^{n-1} \exp \left(a_{l}\right)} \tag{2}
\end{align*}
$$

for model estimated parameters $a_{l}$.

## Crab abundance on July ${ }^{\text {st }}$

Summer (01 July) crab abundance of new and oldshells consists of survivors of winter commercial and subsistence crab fisheries and natural mortality from 01Feb to 01July:

$$
\begin{align*}
N_{s, l t} & =\left(N_{w, l t-1}-C_{w, t-1} P_{w, n, l t-1}-C_{p, t} P_{p, n, l t-1}-D_{w, n, l, t-1}-D_{p, n, l, t-1}\right) e^{-0.42 M_{l}} \\
O_{s, l t} & =\left(O_{w, l t-1}-C_{w, t-1} P_{w, o, l t-1}-C_{p, t} P_{p, o, l t-1}-D_{w, o, l, t-1}-D_{p, o, l, t-1}\right) e^{-0.42 M_{l}} \tag{3}
\end{align*}
$$

where
$N_{s, l, t}, O_{s, l, t}$ : summer abundances of newshell and oldshell crab in length class $l$ in year $t$,
$N_{w, l, t-1}, O_{w, l, t-1}$ : winter abundances of newshell and oldshell crab in length class $l$ in year $t-1$,
$C_{w, t-1}, C_{p, t-1}$ : total winter commercial and subsistence catches in year $t-1$,
$P_{w, n, l, t-1}, P_{w, o l, t-1}$ : Proportion of newshell and oldshell length class $l$ crab in year $t-1$, harvested by winter commercial fishery,
$P_{p, n, l, t-1}, P_{p, o, l, t-1}$ : Proportion of newshell and oldshell length class $l$ crab in year $t-1$, harvested by winter subsistence fishery,
$D_{w, n, l, t-1}, D_{w, o, l, t-1}$ : Discard mortality of newshell and oldshell length class $l$ crab in winter commercial fishery in year $t-1$,
$D_{p, n, l, t-1}, D_{p, o, l, t-1}$ : Discard mortality of newshell and oldshell length class $l$ crab in winter subsistence fishery in year $t-1$,
$M_{l}$ : instantaneous natural mortality in length class $l$,
0.42 : proportion of the year from Feb 1 to July 1 is 5 months.

Length proportion compositions of winter commercial catch $\left(P_{w, n, l, t}, P_{w, o l, t}\right)$ in year $t$ were estimated as:

$$
\begin{align*}
& P_{w, n, l t}=N_{w, l t} S_{w, l} P_{l g, l} / \sum_{l=1}\left[\left(N_{w, l t}+O_{w, l t}\right) S_{w, l} P_{l g, l}\right]  \tag{4}\\
& P_{w, o, l t}=O_{w, l t} S_{w, l} P_{l g, l} / \sum_{l=1}\left[\left(N_{w, l t}+O_{w, l t}\right) S_{w, l} P_{l g, l}\right]
\end{align*}
$$

where
$P_{l g, l}$ : the proportion of legal males in length class $l$,
$S_{w, l}$ : Selectivity of winter fishery pot.

Subsistence fishery does not have a size limit; however, crab of size smaller than length class 3 are generally not retained. Hence, we assumed proportion of length composition $l=1$ and 2 as 0 , and estimated length compositions ( $l \geq 3$ ) as follows

$$
\begin{align*}
& P_{p, n, l t}=N_{w, l t} S_{w, l} / \sum_{l=3}\left[\left(N_{w, l t}+O_{w, l t}\right) S_{w, l}\right]  \tag{5}\\
& P_{p, o, l t}=O_{w, l t} S_{w, l} / \sum_{l=3}\left[\left(N_{w, l t}+O_{w, l t}\right) S_{w, l}\right]
\end{align*}
$$

## Crab abundance on Feb 1st

Newshell Crab: Abundance of newshell crab of year $t$ and length-class $l$ ( $N_{w, l, t}$ ) year-t consist of: (1) new and oldshell crab that survived the summer commercial fishery and molted, and (2) recruitment $\left(R_{l, t}\right)$.

$$
\begin{equation*}
N_{w, l, t}=\sum_{l^{\prime}=1}^{l^{\prime}=l} G_{l^{\prime}, l}\left[\left(N_{s, l^{\prime}, t-1}+O_{s, l^{\prime}, t-1}\right) e^{-y_{c} M_{l}}-C_{s, t}\left(P_{s, n, l^{\prime}, t-1}+P_{s, o, l^{\prime}, t-1}\right)-D_{l^{\prime}, t-1}\right] m_{l^{\prime}} e^{-\left(0.58-y_{c}\right) M_{l}}+R_{l, t} \tag{6}
\end{equation*}
$$

Oldshell Crab: Abundance of oldshell crabs of year $t$ and length-class $l\left(O_{w, l, t}\right)$ consists of the nonmolting portion of survivors from the summer fishery:

$$
\begin{equation*}
O_{w, l, t}=\left[\left(N_{s, l, t-1}+O_{s, l, t-1}\right) e^{-y_{c} M_{l}}-C_{s, t}\left(P_{s, n, l, t-1}+P_{s, o, l, t-1}\right)-D_{l, t-1}\right]\left(1-m_{l}\right) e^{-\left(0.58-y_{c}\right) M_{l}} \tag{7}
\end{equation*}
$$

where
$G_{l, l}$ : a growth matrix representing the expected proportion of crabs growing from length class $l$ to length class $l$
$C_{s, t}$ : total summer catch in year $t$
$P_{s, n, l, t}, P_{s, o, l, t}$ : proportion of summer catch for newshell and oldshell crabs of length class $l$ in year $t$, $D_{l, t}$ : summer discard mortality of length class $l$ in year $t$,
$m_{l}$ : molting probability of length class $l$,
$y_{c}$ : the time in year from July 1 to the mid-point of the summer fishery,
0.58 : Proportion of the year from July $1^{\text {st }}$ to Feb $1^{\text {st }}$ is 7 months is 0.58 year,
$R_{l, t}$ recruitment into length class $l$ in year $t$.

## Discards

Discards are crabs that were caught by fisheries but were not retained, which consists of summer commercial, winter commercial and winter subsistence.
Summer and winter commercial discards
In summer $\left(D_{l, t}\right)$ and winter ( $D_{w, n, l, t}, D_{w, o, l, t}$ ) commercial fisheries, sublegal males ( $<4.75$ inch CW and $<5.0$ inch CW since 2005) are discarded. Those discarded crabs are subject to handling mortality. The number of discards was not directly observed, and thus was estimated from the model as: Observed Catch x (estimated abundance of crab that are not caught by commercial pot)/(estimated abundance of crab that are caught by commercial pot)

Model discard mortality in length-class $l$ in year $t$ from the summer and winter commercial pot fisheries is given by

$$
\begin{gather*}
D_{l, t}=C_{s, t} \frac{\left(N_{s, l, t}+O_{s, l, t}\right) S_{s, l}\left(1-P_{l g, l}\right)}{\sum_{l}\left(N_{s, l, t}+O_{s, l, t}\right) S_{s, l} P_{l g, l}} h m_{s} \text { (Baseline model) }  \tag{8}\\
D_{l, t}=C_{s, t} \frac{\left(N_{s, l, t}+O_{s, l, t}\right) S_{s, l}\left(1-S_{r, l}\right)}{\sum_{l}\left(N_{s, l, t}+O_{s, l, t}\right) S_{s, l} S_{r, l}} h m_{s} \text { (Alternative model) } \\
D_{w, n, l, t}=C_{w, t} \frac{N_{w, l, t} S_{w, l}\left(1-P_{l g, l}\right)}{\sum_{l}\left(N_{w, l, t}+O_{w, l, t}\right) S_{w, l} P_{l g, l}} h m_{w}  \tag{9}\\
D_{w, o, l, t}=C_{w, t} \frac{O_{w, l, t} S_{w, l}\left(1-P_{l g, l}\right)}{\sum_{l}\left(N_{w, l, t}+O_{w, l, t}\right) S_{w, l} P_{l g, l}} h m_{w} \tag{10}
\end{gather*}
$$

where
$h m_{s}$ : summer commercial handling mortality rate assumed to be 0.2 , $h m_{w}$ : winter commercial handling mortality rate assumed to be 0.2 ,
$S_{s, l}$ : Selectivity of the summer commercial fishery,
$S_{w, l}$ : Selectivity of the winter commercial fishery,
$S_{r, l}$ : Retention selectivity of the summer commercial fishery,

Winter subsistence Discards

Discards (unretained) of winter subsistence fishery is reported in a permit survey $\left(C_{d, t}\right)$, though its size composition is unknown. We assumed that subsistence fishers discarded all crabs of length classes 1-2.

$$
\begin{align*}
D_{p, n, l, t} & =C_{d, t} \frac{N_{w, l, t} S_{w, l}}{\sum_{l=1}^{2}\left(N_{w, l, t}+O_{w, l, t}\right) S_{w, l}} h m_{w}  \tag{11}\\
D_{p, o l, t, t} & =C_{d, t} \frac{O_{w, l, t} S_{w, l}}{\sum_{l=1}^{2}\left(N_{w, l, t}+O_{w, l, t}\right) S_{w, l}} h m_{w} \tag{12}
\end{align*}
$$

$C_{d, t}$ : Winter subsistence discards catch,

## Recruitment

Recruitment of year $t, R_{t}$, is a stochastic process around the geometric mean, $R_{0}$ :

$$
\begin{equation*}
R_{t}=R_{0} e^{\tau_{t}}, \tau_{t} \sim N\left(0, \sigma_{R}^{2}\right) \tag{13}
\end{equation*}
$$

$R_{t}$ of the last year was assumed to be an average of previous 5 years: $R_{t}=\left(R_{t-1}+R_{t-2}+R_{t-3}+R_{t-4}+\right.$ $\left.R_{t-5}\right) / 5$.
$R_{t}$ was assumed to be newshell crab of immature (<94mm) length classes 1 to $r$ :

$$
\begin{equation*}
R_{r, t}=p_{r} R_{t} \tag{14}
\end{equation*}
$$

where $r$ takes multinomial distribution, same as the equation (2)

## Molting Probability

Molting probability for length class $l, m_{l}$, was estimated as an inverse logistic function of lengthclass mid carapace length $(L)$ and parameters $(\alpha, \beta)$ where $\beta$ corresponds to $L_{50}$.

$$
\begin{equation*}
m_{l}=\frac{1}{1+e^{\alpha(L-\beta)}} \tag{15}
\end{equation*}
$$

Trawl net, summer commercial pot, retention selectivity
Trawl and summer commercial pot selectivity was assumed to be a logistic function of mid-lengthclass, constrained to be 0.999 at the largest length-class $\left(L_{\text {max }}\right)$ :

$$
\begin{equation*}
S_{l}=\frac{1}{1+e^{\left(\alpha\left(L_{\max }-L\right)+\ln (1 / 0.099-1)\right)}} \tag{16}
\end{equation*}
$$

## Alternative Summer commercial pot, retention selectivity

Summer pot selectivity was assumed to be a logistic function of length-class mid carapace length $(L)$ and parameters $(\alpha, \beta)$ where $\beta$ corresponds to $L_{50}$.

$$
\begin{equation*}
S_{c, l}=\frac{1}{1+e^{-\alpha(L-\beta)}} \tag{16'}
\end{equation*}
$$

## Winter pot selectivity

Winter pot selectivity was assumed to be a dome-shaped with inverse logistic function of lengthclass mid carapace length $(L)$ and parameters $(\alpha, \beta)$ where $\beta$ corresponds to $L_{50}$.

$$
\begin{equation*}
S_{w, l}=\frac{1}{1+e^{\alpha(L-\beta)}} \tag{17}
\end{equation*}
$$

Selectivity of the length classes $S_{w, s}\left(\mathrm{~S}=l_{1}, l_{2}\right)$ were individually estimated.

## Growth transition matrix

The growth matrix $G_{l, l}$ (the expected proportion of crab molting from length class $l$ ' to length class $l$ ) was assumed to be normally distributed:

$$
G_{l^{\prime}, l}= \begin{cases}\frac{\int_{l m_{l}-h}^{l m_{l}+h} N\left(L \mid \mu_{l^{\prime}}, \sigma^{2}\right) d L}{\sum_{l=1}^{n} \int_{l m_{l}-h}^{l m_{l}+h} N\left(L \mid \mu_{l^{\prime}}, \sigma^{2}\right) d L} & \text { when } l \geq l^{\prime}  \tag{18}\\ 0 & \text { when } l<l^{\prime}\end{cases}
$$

Where

$$
\begin{aligned}
& N\left(x \mid \mu_{l^{\prime}}, \sigma^{2}\right)=\frac{1}{\sqrt{2 \pi \sigma^{2}}} \exp \left(-\frac{\left(L-\mu_{l^{\prime}}\right)^{2}}{\sigma^{2}}\right) \\
& \operatorname{lm}_{l}=L_{1}+s t \cdot l \\
& \mu_{l}=L_{1}+\beta_{0}+\beta_{1} \cdot l
\end{aligned}
$$

## Observation model

## Summer trawl survey abundance

Modeled trawl survey abundance of year $t\left(B_{s t, t}\right)$ is July $1^{\text {st }}$ abundance subtracted by summer commercial fishery harvest occurring from July $1^{\text {st }}$ to the mid-point of summer trawl survey, multiplied by natural mortality occurring between the mid-point of commercial fishery date and trawl survey date, and multiplied by trawl survey selectivity. For the first year (1976) trawl survey, the commercial fishery did not occur.

$$
\begin{equation*}
\hat{B}_{s t, t}=\sum_{l}\left[\left(N_{s, l, t}+O_{s, l, t}\right) e^{-y_{c} M_{l}}-C_{s, t} P_{c, t}\left(P_{s, n, l, t}+P_{s, o l, t}\right)\right] e^{-\left(y_{s}-y_{c}\right) M_{l}} S_{s t, l} \tag{19}
\end{equation*}
$$

where
$y_{s t}$ : the time in year from July 1 to the mid-point of the summer trawl survey,
$y_{c}$ : the time in year from July 1 to the mid-point for the catch before the survey, $\left(y_{s t}>y_{c}\right.$ : Trawl survey starts after opening of commercial fisheries),
$P_{c, t}$ : the proportion of summer commercial crab harvested before the mid-point of trawl survey date.
$S_{s t, l}$ : Selectivity of the trawl survey.

## Winter pot survey CPUE

Winter pot survey cpue $\left(f_{w t}\right)$ was calculated with catchability coefficient $q$ and exploitable abundance:

$$
\begin{equation*}
\hat{f}_{w t}=q_{w} \sum_{l}\left[\left(N_{w, l, t}+O_{w, l, t}\right) S_{w, l}\right] \tag{20}
\end{equation*}
$$

## Summer commercial CPUE

Summer commercial fishing CPUE $\left(f_{t}\right)$ was calculated as a product of catchability coefficient $q$ and mean exploitable abundance minus one half of summer catch, $\mathrm{A}_{\mathrm{t}}$ :

$$
\begin{equation*}
\hat{f}_{t}=q_{i}\left(A_{t}-0.5 C_{t}\right) \tag{21}
\end{equation*}
$$

Because the fishing fleet and pot limit configuration changed in 1993, $q_{1}$ is for fishing efforts before

1993, $q_{2}$ is from 1994 to present.

## Baseline model

Where $A_{t}$ is exploitable legal abundance in year $t$, estimated as

$$
\begin{align*}
A_{t} & =\sum_{l}\left[\left(N_{s, l, t}+O_{s, l t}\right) S_{s, l} P_{\mathrm{lg}, l}\right] \quad \text { (Baseline model) }  \tag{22}\\
A_{t} & =\sum_{l}\left[\left(N_{s, l t}+O_{s, l t}\right) S_{s, l} S_{r, l}\right] \text { (Alternative model) }
\end{align*}
$$

Summer pot survey abundance (Removed from likelihood components)
Abundance of $t$-th year pot survey was estimated as

$$
\begin{equation*}
\hat{B}_{p, t}=\sum_{l}\left[\left(N_{s, l, t}+O_{s, l, t}\right) e^{-y_{p} M_{l}}\right] S_{p, l} \tag{23}
\end{equation*}
$$

Where
$y_{p}$ : the time in year from July 1 to the mid-point of the summer pot survey.
Length composition

## Summer commercial catch

Length compositions of the summer commercial catch for new and old shell crabs $P_{s, n, l, t}$ and $P_{s, o, l, t}$, were modeled based on the summer population, selectivity, and legal abundance:

$$
\begin{align*}
& \hat{P}_{s, n, l, t}=N_{s, l, t} S_{s, l} P_{\text {lg }, l} / A_{t} \\
& \hat{P}_{s, o, l, t}=O_{s, l, t} S_{s, l} P_{\mathrm{g}, l} / A_{t} \quad \text { (Baseline model) }  \tag{24}\\
& \hat{P}_{s, n, l, t}=N_{s, l, l} S_{s, l} S_{r, l} / A_{t} \\
& \hat{P}_{s, o, l, t}=O_{s, l, t} S_{s, l} S_{r, l} / A_{t}
\end{align*}
$$

Summer commercial fishery discards (Base model)
Length/shell compositions of observer discards were modeled as

$$
\begin{align*}
& \hat{P}_{b, n, l t}=N_{s, l t} S_{s, l}\left(1-P_{l s, l}\right) / \sum_{l}\left[\left(N_{s, l t}+O_{s, l t}\right) S_{s, l}\left(1-P_{l g, l}\right)\right]  \tag{25}\\
& \hat{P}_{b, o, l t}=O_{s, l t} S_{s, l}\left(1-P_{l g, l}\right) / \sum_{l}\left[\left(N_{s, l t}+O_{s, l t}\right) S_{s, l}\left(1-P_{l s, l}\right)\right]
\end{align*}
$$

## Length/shell compositions of observer discards were modeled as

$$
\begin{align*}
& \hat{P}_{t, n, l, t}=N_{s, l, t} S_{s, l} / \sum_{l}\left[\left(N_{s, l, t}+O_{s, l t}\right) S_{s, l}\right] \\
& \hat{P}_{t, o, l, t}=O_{s, l, t} S_{s, l} / \sum_{l}\left[\left(N_{s, l, t}+O_{s, l t}\right) S_{s, l}\right]
\end{align*}
$$

## Summer trawl survey

Proportions of newshell and oldshell crab, $P_{s t, n, l, t}$ and $P_{s t, o l, t}$ were given by

$$
\begin{align*}
\hat{P}_{s t, n, l, t} & =\frac{\left[N_{s, l, t} e^{-y_{c} M_{l}}-C_{s, t} P_{c, t} \hat{P}_{s, n, l^{\prime} t}\right] e^{-\left(y_{s, t}-y_{c}\right) M_{l}} S_{s t, l}}{\sum_{l}\left[\left(N_{s, l, t}+O_{s, l, t}\right) e^{-y_{c} M_{l}}-C_{s, t} P_{c, t}\left(\hat{P}_{s, n, l^{\prime}, t}+\hat{P}_{s, o, l^{\prime} t}\right)\right] e^{-\left(y_{s}-y_{c}\right) M_{l}} S_{s t, l}}  \tag{26}\\
\hat{P}_{s t, o l, t} & =\frac{\left[O_{s, l, t} e^{-y_{c} M_{l}}-C_{s, t} \hat{P}_{s, o, l, t} P_{c, t}\right] e^{-\left(y_{s}-y_{c}\right) M_{l}} S_{s t, l}}{\sum_{l}\left[\left(N_{s, l, t}+O_{s, l, t}\right) e^{-y_{c} M_{l}}-C_{s, t} P_{c, t}\left(\hat{P}_{s, n, l, t}+\hat{P}_{s, o, l, t}\right)\right] e^{-\left(y_{s t}-y_{c}\right) M_{l}} S_{s t, l}}
\end{align*}
$$

## Winter pot survey

Winter pot survey length compositions for newshell and oldshell crab, $P_{s w, n, l, t}$ and $P_{s w, o, l, t}(l \geq 1)$ were calculated as

$$
\begin{align*}
& \hat{P}_{s w, n, l t}=N_{w, l t} S_{w, l} / \sum_{l}\left[\left(N_{w, l t}+O_{w, l t}\right) S_{w, l}\right]  \tag{27}\\
& \hat{P}_{s w, o, l t}=O_{w, l t} S_{w, l} / \sum_{l}\left[\left(N_{w, l t}+O_{w, l t}\right) S_{w, l}\right]
\end{align*}
$$

Spring Pot survey 2012-2015
Winter pot survey length compositions for newshell and oldshell crab, $P_{s v, n, l, t}$ and $P_{s w, o l, t}(l \geq 1)$ were assumed to be supper crab population caught by winter pot survey gears

$$
\begin{align*}
& \hat{P}_{s p, n, l t}=N_{s, l t} S_{w, l} / \sum_{l}\left[\left(N_{s, l t}+O_{s, l t}\right) S_{w, l}\right]  \tag{28}\\
& \hat{P}_{s p, o, l t}=O_{s, l t} S_{s, l} / \sum_{l}\left[\left(N_{s, l t}+O_{s, l t}\right) S_{w, l}\right]
\end{align*}
$$

## Estimates of tag recovery

The proportion of released tagged length class $l$ ' crab recovered after $t$-th year with length class of $l$
by a fishery of $s$ - $t h$ selectivity $\left(S_{l}\right)$ was assumed to be proportional to the growth matrix, catch selectivity, and molting probability $\left(m_{l}\right)$ as

$$
\begin{equation*}
\hat{P}_{l, l, t, s}=\frac{S_{l} \cdot\left[X^{t}\right]_{l, l}}{\sum_{l=1}^{n} S_{l} \cdot\left[X^{t}\right]_{l, l}} \tag{29}
\end{equation*}
$$

where $X$ is a molting probability adjusted growth matrix with each component consisting of

$$
X_{l^{\prime}, l}=\left\{\begin{array}{c}
m_{l^{\prime}} \cdot G_{l^{\prime}, l} \quad \text { when } l^{\prime} \neq l  \tag{30}\\
m_{l} \cdot G_{l, l}+\left(1-m_{i}\right) \text { when } l^{\prime}=l
\end{array}\right.
$$

b. Software used: AD Model Builder (Fournier et al. 2012).

## c. Likelihood components.

Under assumptions that measurement errors of annual total survey abundances and summer commercial fishing efforts follow lognormal distributions and each type of length composition has a multinomial error structure (Fournier and Archibald 1982; Methot 1989), the log-likelihood function is

$$
\begin{align*}
& \sum_{i=1}^{i=4} \sum_{t=1}^{t=n_{i}} K_{i, t}\left[\sum_{l=1}^{l=n} P_{i, l, t} \ln \left(\hat{P}_{i, l, t}+\kappa\right)-\sum_{l=1}^{l=n} P_{i, l, t} \ln \left(P_{i, l, t}+\kappa\right)\right] \\
& -\sum_{t=1}^{t=n_{i}} \frac{\left[\ln \left(q \cdot \hat{B}_{i, t}+\kappa\right)-\ln \left(B_{i, t}+\kappa\right)\right]^{2}}{2 \cdot \ln \left(C V_{i, t}^{2}+1\right)} \\
& -\sum_{t=l}^{t=n_{i}}\left[\frac{\ln \left[\ln \left(C V_{t}^{2}+l\right)+w_{t}\right]}{2}+\frac{\left[\ln \left(\hat{f}_{t}+\kappa\right)-\ln \left(f_{t}+\kappa\right)\right]^{2}}{2 \cdot\left[\ln \left(C V_{t}^{2}+l\right)+w_{t}\right]}\right]  \tag{32}\\
& -\sum_{t=1} \frac{\tau_{t}^{2}}{2 \cdot S D R^{2}} \\
& +W \sum_{s=1}^{s=2} \sum_{t=1}^{t=3} \sum_{l^{\prime}=1}^{l^{\prime}=n} K_{l^{\prime}, t, s}\left[\sum_{l=1}^{l=n} P_{l^{\prime}, l, t} \ln \left(\hat{P}_{l^{\prime}, l, t, s}+\kappa\right)-\sum_{l=1}^{l=n} P_{l^{\prime}, l, t} \ln \left(\boldsymbol{P}_{l^{\prime} \neq t, t, s}+\kappa\right)\right]
\end{align*}
$$

where
$i$ : length/shell compositions of :
1 triennial summer trawl survey,
2 annual winter pot survey,
3 summer commercial fishery retained catch,
4 observer discards or total catch during the summer fishery
5 spring pot survey.
$K_{i, t}$ : the effective sample size of length/shell compositions for data set $i$ in year $t$,
$P_{i, l, t}$ : observed and estimated length compositions for data set $i$, length class $l$, and year $t$.
$\kappa$ : a constant equal to 0.0001 ,
$C V$ : coefficient of variation for the survey abundance,
$B_{i, k, t}$ : observed and estimated annual total abundances for data set $i$ and year $t$,
$f_{t}$ : observed and estimated summer fishing CPUE,
$w_{t}^{2}$ : extra variance factor,
$S D R$ : Standard deviation of recruitment $=0.5$,
$K_{l, t}$ : sample size of length class $l$ ' released and recovered after $t$-th in year,
$P_{l^{\prime}, l, t, s}$ : observed and estimated proportion of tagged crab released at length $l$ ' and recaptured at
length $l$, after $t$-th year by commercial fishy pot selectivity $s$,
$W$ : weighting for the tagging survey likelihood
It is generally believed that total annual commercial crab catches in Alaska are fairly accurately reported. Thus, total annual catch was assumed known.

## d. Parameter estimation framework:

i. Parameters Estimated Independently

The following parameters were estimated independently: natural mortality ( $M=0.18$ ), proportions of legal males by length group.

Natural mortality was based on an assumed maximum age, $t_{\max }$, and the $1 \%$ rule (Zheng 2005):

$$
M=-\ln (p) / t_{\max }
$$

where $p$ is the proportion of animals that reach the maximum age and is assumed to be 0.01 for the $1 \%$ rule (Shepherd and Breen 1992, Clarke et al. 2003). The maximum age of 25, which was used to estimate $M$ for U.S. federal overfishing limits for red king crab stocks results in an estimated $M$ of 0.18 . Among the 199 recovered crabs from the tagging returns during 1991-2007 in Norton Sound, the longest time at liberty was 6 years and 4 months from a crab tagged at 85 mm CL. The crab was below the mature size and was likely less than 6 years old when tagged. Therefore, the maximum age from tagging data is about 12, which does not support the maximum age of 25 chosen by the CPT.

Proportions of legal males ( $\mathrm{CW}>4.75$ inches) by length group were estimated from the ADF\&G trawl data 1996-2011 (Table 11).

## ii. Parameters Estimated Conditionally

Estimated parameters are listed in Table 10. Selectivity and molting probabilities based on these estimated parameters are summarized in Tables 11.

A likelihood approach was used to estimate parameters

## e. Definition of model outputs.

i. Estimate of mature male biomass (MMB) is on February $1^{\text {st }}$ and is consisting of the biomass of male crab in length classes 4 to 8

$$
M M B=\sum_{l=4}\left(N_{w, l,}+O_{w, l}\right) w m_{l}
$$

$w m i$ : mean weight of each length class (Table 11).
ii. Projected legal male biomass for winter and summer fishery OFL was calculated as

$$
\text { Legal_B }=\sum_{l}\left(N_{w, l}+O_{w, l}\right) S_{s, l} P_{l g, l} w m_{l} \text { Baseline model }
$$

$$
\text { Legal_B } B=\sum_{l}\left(N_{w, l}+O_{w, l}\right) S_{s, l} S_{r, l} w m_{l} \text { Alternative model }
$$

iii. Recruitment: the number of males in length classes 1,2 , and 3 .
iv.

## f. OFL

The Norton Sound red king crab fishery consists of two distinct fisheries: winter and summer. The two fisheries are discontinuous with 5 months between the two fisheries during which natural mortalities occur. To incorporate this fishery, the CPT in 2016 recommended the following formula:
$O F L_{r}=$ Winter harvest (Hw) + Summer harvest (Hs)
And

$$
\begin{equation*}
p=\frac{H w}{O F L_{r}} \tag{2}
\end{equation*}
$$

Where $p$ is a specific proportion of winter crab harvest to total (winter + summer) harvest At given fishery mortality (Fofl), Winter harvest is a fishing mortality

$$
\begin{equation*}
H w=\left(1-e^{-x F}\right) B_{w} \tag{3}
\end{equation*}
$$

$$
\begin{equation*}
H s=\left(1-e^{-(1-x) \cdot F}\right) B_{s} \tag{4}
\end{equation*}
$$

where $\mathrm{B}_{\mathrm{s}}$ is a summer crab biomass after winter fishery and $\mathrm{x}(0 \leq \mathrm{x} \leq 1)$ is a fraction that satisfies equation (2)
Since $B_{s}$ is a summer crab biomass after winter fishery and 5 months of natural morality ( $e^{-0.42 M}$ )

$$
\begin{align*}
& B_{s}=\left(B_{w}-H w\right) e^{-0.42 M}  \tag{5}\\
& =\left(B_{w}-\left(1-e^{-x \cdot F}\right) B_{w}\right) e^{-0.42 M} \\
& =B_{w} e^{-x \cdot F-0.42 M}
\end{align*}
$$

Substituting $0.42 M$ to $m$, summer harvest is

$$
\begin{align*}
& H s=\left(1-e^{-(1-x) \cdot F}\right) B_{s}  \tag{6}\\
& =\left(1-e^{-(1-x) \cdot F}\right) B_{w} e^{-x \cdot F-m}=\left(e^{-(x \cdot F+m)}-e^{-(F+m)}\right) B_{w}
\end{align*}
$$

Thus, OFL is

$$
\begin{align*}
& \text { OFL }=H w+H s=\left(1-e^{-x F}\right) B_{w}+\left(e^{-(x \cdot F+m)}-e^{-(F+m)}\right) B_{w}  \tag{7}\\
& =\left(1-e^{-x F}+e^{-(x F+m) \cdot}-e^{-(F+m)}\right) B_{w} \\
& =\left[1-e^{-(F+m) \cdot}-\left(1-e^{-m w}\right) e^{-x F w}\right] B_{w}
\end{align*}
$$

Combining (2) and (7),

$$
\begin{equation*}
p=\frac{H w}{O F L_{r}}=\frac{\left(1-e^{-x F}\right) B_{w}}{\left[1-e^{-(F+m) \cdot}-\left(1-e^{-m \cdot}\right) e^{-x F \cdot}\right] B_{w}} \tag{8}
\end{equation*}
$$

Solving (8) for x

$$
\begin{aligned}
& \left(1-e^{-x F}\right)=p\left[1-e^{-(F+m)}-\left(1-e^{-m \cdot}\right) e^{-x F \cdot}\right] \\
& e^{-x F}-p\left(1-e^{-m \cdot}\right) e^{-x F \cdot}=1-p\left[1-e^{-(F+m)}\right] \\
& {\left[1-p\left(1-e^{-m \cdot}\right)\right] e^{-x F \cdot}=1-p\left[1-e^{-(F+m)}\right]} \\
& e^{-x F .}=\frac{1-p\left[1-e^{-(F+m)}\right]}{1-p\left(1-e^{-m \cdot}\right)}
\end{aligned}
$$

Combining (7) and (9), and substituting back,
revised retained OFL is

$$
O F L=L_{\text {Legal }}^{-} B_{w}\left(1-e^{-\left(F_{\text {orL }}+0,42 M\right)}-\left(1-e^{-0.42 M}\right)\left(\frac{1-p\left(1-e^{-\left(F_{\text {orL }}+0.42 M\right)}\right)}{1-p\left(1-e^{-0.42 M}\right)}\right)\right)
$$

Further combining (3) and (9), Winter fishery harvest rate (Fw) i

$$
\begin{align*}
& F w=\left(1-e^{-x \cdot F}\right)=1-\frac{1-p\left[1-e^{-(F+m)}\right]}{1-p\left(1-e^{-m}\right)}=\frac{1-p\left(1-e^{-m}\right)-1+p\left[1-e^{-(F+m)}\right]}{1-p\left(1-e^{-m}\right)}  \tag{10}\\
& =\frac{p\left(e^{-m}-e^{-(F+m)}\right)}{1-p\left(1-e^{-m \cdot}\right)}=\frac{p\left(1-e^{-F}\right) e^{-0.42 M .}}{1-p\left(1-e^{-0.42 M \cdot}\right)}
\end{align*}
$$

Summer fishery harvest rate (Fs) is

$$
\begin{align*}
& F s=\left(e^{-(x \cdot F+m)}-e^{-(F+m)}\right)=\left(e^{-x \cdot F}-e^{-F}\right) e^{-m}  \tag{11}\\
& =\left(\frac{1-p\left[1-e^{-(F+m)}\right]}{1-p\left(1-e^{-m \cdot}\right)}-e^{-F}\right) e^{-m} \\
& =\left(\frac{1-p\left[1-e^{-(F+m)}\right]-e^{-F}+p\left(e^{-F}-e^{-(F+m \cdot)}\right)}{1-p\left(1-e^{-m \cdot}\right)}\right) e^{-m} \\
& =\left(\frac{1-p+p e^{-(F+m) \cdot}-e^{-F}+p e^{-F}-p e^{-(F+m \cdot)}}{1-p\left(1-e^{-m \cdot}\right)}\right) e^{-m} \\
& =\frac{(1-p)\left(1-e^{-F}\right) e^{-m}}{1-p\left(1-e^{-m \cdot}\right)}=\frac{(1-p)\left(1-e^{-F}\right) e^{-0.24 M}}{1-p\left(1-e^{-0.24 M \cdot}\right)}
\end{align*}
$$

## Appendix B

# Norton Sound Red King Crab CPUE Standardization 

Note: This is an update of model by G. Bishop (SAFE 2013).

## Methods

## Data Source \& Cleaning

Commercial fishery harvest data were obtained from a fish ticket database, which included: Landing Date, Fish Ticket Number, Vessel Number, Permit Fishery ID, Statistical Area(s) fished, Effort, and Number and Pounds of Crab harvested (Table A2-1,2,3, Figure A2-1). Fish ticket database may have multiple entries of identical Fish Ticket Number, Vessel Number, Permit Fishery ID, and Statistical Area. In those cases, at least one Effort data are missing or zero with the Number and Pounds of Crab harvested. These entries indicate that crabs were either retained from commercial fishery (i.e., not sold), or dead loss.

Following data cleaning and combining methods were conducted.

1. Sum crab number and efforts by Fish Ticket Number, Vessel Number, Permit Fishery ID, Statistical Area
2. Remove data of missing or zero Efforts, Number of Crab, Pounds of Crab (Those are considered as true missing data)
3. Calculate CPUE as Number of Crab/Effort

## Data Censoring

During 1977-92 period, vessels of 1 year of operation and/or 1 delivery per year harvested 20-90\% of crabs (Table A2-5, Figure A2-2). For instance, all vessels did only 1 delivery in 1989, and in 1988 64\% of crabs were harvested by 1 vessel that did only 1 delivery. On the other hand, during the 1993-2017
period of post super-exclusive fishery status, the majority of commercial crab fishery and harvest was done by vessels with more than 5 years of operations and more than 5 deliveries per year. For 1977 1992, censoring was made for vessels of more than 2 years of operations. Increasing deliveries to more than one would result in no estimates for some years. For 1993 - 2018, censoring was made for vessels of more than 5 years of operations and 5 deliveries per year.

## Analyses

## A GLM was constructed as

$$
\ln (C P U E)=Y R+P D+V S L+M S A+W O Y+P F
$$

Where YR: Year, PD: Fishery periods (1977-1992, 1993-2004,2005-2018), VSL: Vessel, MSA: Statistical Area, WOY: Week of Year, PF: Permit vs open fishery (Table 1). All variables were treated as categorical. Inclusion of interaction terms were not considered because they were absent (SAFE 2013).

For selection of the best model, forward and backward stepwise selection was conducted. (R step function)

```
fit <- glm(L.CPUE.NO ~ factor(YR) + factor(VSL) + factor(WOY) +
factor(MSA) + factor(PF),data=NSdata.C)
step <- step(fit, direction='both', trace = 10)
best.glm<-glm(formula(step), data=NSdata.C)
```

The analyses were conducted for both censored and full data.
Generally, censoring had little effects on standardized CPUE.

Table B-1. List of variables in the fish ticket database. Variables in bold face were used for generalized linear modeling.

| Variable | Description |
| :--- | :--- |
| YR | Year of commercial fishery |
| VSL | Unique vessel identification number |
| Fish Ticket Number | Unique delivery to a processor by a vessel. |
| PF | Unique Permit Fishery categories |
| Statistical Area | Unique fishery area. |
| MOA | Modified statistical area, combining each statistical area into 4 larger |
|  | areas: Inner, Mid, Outer, Outer North |
| Fishing beginning date | Date of pots set |
| Landing date | Date of crab landed to processor |
| WOY | Week of Landing Date (calculated) |
| Effort | The number of pot lift |
| Crab Numbers | Total number of crabs harvested from pots |
| Crab Pounds | Total pounds of crab harvested from pots |
| $\ln (\mathbf{C P U E})$ | $\ln ($ Crab Numbers/Effort) (calculated) |

Table B-2. Permit fisheries, descriptions, and years with deliveries for Norton Sound summer commercial red king crab harvest data.

| Permit <br> fishery | Type | Description | Years |
| :--- | :--- | :--- | :---: |
| K09Q | Open access | KING CRAB , POT GEAR VESSEL UNDER 60', BERING SEA | $1994-2002$ |

## Appendix C2: Model 1 Results

Figure C2-1. QQ Plot of Trawl survey and Commercial CPUE.

Figure C2-2: Implied effective samples. Figures in the first column show implied effective sample size ( x -axis) vs. frequency ( y -axis).
Vertical solid line is the mean implied effective sample size.
The second column show input sample size ( x -axis) vs. implied effective sample size ( y -axis). Dashed line indicates linear regression slope, and solid line is 1:1 line. The third column show year ( x -axis) vs. implied effective sample size ( y -axis).

Figure C2-3. Molting probability and trawl/pot selectivity. X-axis is carapace length.

Figure C2-4. Estimated trawl survey male abundance (crab >= 64 mm CL). Observed: White: NOAA Trawl Survey, Red: ADG\&G Trawl Survey

Figure C2-5. Estimated abundance of legal males from 1976-2015.

Figure C2-6. Estimated abundance of Mature Male Biomass from 1976-2019. Dash line shows Bmsy (Average MMB of 1980-2019).

## Summer commercial standardized cpue

Figure C2-7. Summer commercial standardized cpue 1977-2018.

Figure C2-8. Total catch and estimated harvest rate 1976-2018.

Figure C2-9. Predicted (dashed line) vs. observed (dots) length class proportions for commercial catch. Bladk: New Shell, Red: Old Shell

## CL mm

Figure C2-10. Predicted (dashed line) vs. observed (black dots) length class proportions for the winter and spring pot survey.

Trawl length: observed vs predicted

Proportion

## CL mm

Figure C2-12. Predicted (dashed) vs. observed (dots) length class proportions for the observer survey.

Figure C2-13. Predicted vs. observed length class proportions for tag recovery data.

Figure C2-13. Bubble plots of predicted and observed length proportions.
Black circle indicates model estimates lower than observed, white circle indicates model estimates higher than observed. Size of circle indicates degree of deviance (larger circle $=$ larger deviance).

Figure C2-14. Bubble plots of predicted and observed length proportions.
Black circle indicates model estimates lower than observed, white circle indicates model estimates higher than observed. Size of circle indicates degree of deviance (larger circle $=$ larger deviance).

# Aleutian Islands Golden King Crab Model-Based Stock Assessment 

May 2018 Crab SAFE DRAFT REPORT

M.S.M. Siddeek ${ }^{1,}$ J. Zheng $^{1}$, C. Siddon ${ }^{1}$, B. Daly ${ }^{2}$, J. Runnebaum ${ }^{1}$ and M.J. Westphal ${ }^{3}$<br>${ }^{1}$ Alaska Department of Fish and Game, Division of Commercial Fisheries, P.O. Box 115526, Juneau, Alaska 99811<br>${ }^{2}$ Alaska Department of Fish and Game, Division of Commercial Fisheries, 351 Research Ct., Kodiak, Alaska 99615<br>${ }^{3}$ Alaska Department of Fish and Game, Division of Commercial Fisheries, PO Box 920587, Dutch Harbor, Alaska 99692.

## Executive Summary

1. Stock

Golden king crab, Lithodes aequispinus, Aleutian Islands, east of $174^{\circ} \mathrm{W}$ longitude (EAG) and west of $174^{\circ} \mathrm{W}$ longitude (WAG).

## 2. Catches

The Aleutian Islands golden king crab commercial fishery has been prosecuted since 1981/82 and opened every year since then. Retained catch peaked in 1986/87 at 2,686 t (5.922,425 lb) and $3,999 \mathrm{t}(8,816,319 \mathrm{lb})$, respectively, for EAG and WAG, but the retained catch dropped sharply from 1989/90 to 1990/91. The fishery has been managed separately east (EAG) and west (WAG) of $174^{\circ} \mathrm{W}$ longitude since 1996/97 and Guideline Harvest Levels (GHLs) of $1,452 \mathrm{t}(3,200,000 \mathrm{lb})$ for EAG and $1,225 \mathrm{t}(2,700,000 \mathrm{lb})$ for WAG were introduced into management for the first time in 1996/97. The GHL was subsequently reduced to $1,361 \mathrm{t}$ (3,000,000 lb beginning in 1998/99 for EAG. The reduced GHLs remained at $1,361 \mathrm{t}$ (3,000,000 lb) for EAG and $1,225 \mathrm{t}(2,700,000 \mathrm{lb})$ for WAG through 2007/08, but were increased to $1,429 \mathrm{t}(3,150,000 \mathrm{lb})$ for EAG and $1,294 \mathrm{t}(2,835,000 \mathrm{lb})$ for WAG beginning with the 2008/09 fishing season following an Alaska Board of Fisheries (BOF) decision. The acronym changed from GHL to TAC (Total Allowable Catch) since crab rationalization in 2005/06. The TACs were further increased by another BOF decision to $1,501 \mathrm{t}(3,310,000$ lb) for EAG and $1,352 \mathrm{t}(2,980,000 \mathrm{lb})$ for WAG beginning with the $2012 / 13$ fishing season.

Catches have been steady since the introduction of GHL/TAC and the fishery has harvested close to TAC levels since 1996/97. These TAC levels were below the ABCs determined under Tier 5 criteria (considering 1991-1995 mean catch for the whole Aleutian Islands region, $3,145 \mathrm{t}(6,933,822 \mathrm{lb})$, as the limit catch) under the most recent crab management plan. The below par fishery performance in WAG in recent years lead to reduction in TAC to $1,014 \mathrm{t}(2,235,000 \mathrm{lb})$, which reflected a $25 \%$ reduction on the TAC for WAG, while the TAC for EAG was kept at the same level, $1,501 \mathrm{t}(3,310,000 \mathrm{lb})$ for the 2015/16 through 2017/18 fishing seasons. In addition to the retained catch that is allotted as TAC, there was retained catch in a cost-recovery fishery towards a $\$ 300,000$ goal in 2013/14 and 2014/15, and towards a $\$ 500,000$ goal in 2015/16 and 2016/17.

Catch per pot lift (CPUE) of retained legal males decreased from the 1980s into the mid1990s, but increased steadily after 1994/95 and increased markedly at the initiation of the

Crab Rationalization program in 2005/06. Although CPUE for the two areas showed similar trends through 2010/11, during 2011/12-2014/15 CPUE trends have diverged (increasing EAG and decreasing WAG). Total retained catch in 2016/17 was $2,593 \mathrm{t}(5,716,180 \mathrm{lb})$ : $1,578 \mathrm{t}(3,479,529 \mathrm{lb})$ from the EAG fishery, which included cost-recovery catch, $1,015 \mathrm{t}$ $(2,236,651 \mathrm{lb})$ from the WAG fishery. Discarded (non-retained) catch occurs mainly during the directed fishery. Although low levels of discarded catch can occur during other crab fisheries, there have been no such fisheries prosecuted since 2004/05, except as surveys for red king crab conducted under a commissioner's permit (and there were none caught during the cooperative red king crab survey performed by industry and ADF\&G in the Adak area in September 2015 (Hilsinger et al. 2016). Estimates of the bycatch mortality during crab fisheries decreased during 1995/96-2005/06, both in absolute value and relative to the retained catch weight, and stabilized during 2005/06-2014/15. Total estimated bycatch mortality during crab fisheries in 2016/17 was $138 \mathrm{t}(303,832 \mathrm{lb})$ for EAG and $92 \mathrm{t}(202,815$ lb) for WAG. Discarded catch also occurs during fixed-gear and trawl groundfish fisheries, but is small relative to that during the directed fishery and the groundfish fisheries are a minor contributor to total fishery mortality. Estimated bycatch mortality during groundfish fisheries in 2016/17 was $3 \mathrm{t}(6,245 \mathrm{lb})$ for EAG and $3 \mathrm{t}(6,800 \mathrm{lb})$ for WAG. A cooperative golden king crab survey was performed by the Aleutian Islands King Crab Foundation (an industry group) and ADF\&G during the EAG fishery in August 2016, by vessels that were simultaneously fishing. During the survey work, adjustments were made to a portion of the gear so escape mechanisms were no longer functional. However, for the purpose of catch accounting for $2016 / 17$, it was assumed that bycatch mortality that occurred during the survey was accounted for by reported discards for the 2016/17 EAG fishery. The cooperative survey was also conducted in August 2017 during the 2017/18 EAG fishery.

## 3. Stock biomass

Estimated mature male biomass (MMB) for EAG under all scenarios decreased from high levels during the 1990s, then systematically increased during the 2000s and 2010s. Estimated MMB for WAG decreased during the late 1980s and 1990s, systematically increased during the 2000s, and decreased for a number of years since 2009. The low levels of MMB for EAG were observed in 1995-1997 and in 1990s for WAG. Slightly increasing trends in MMB were observed since 2014 in both regions. Stock trends reflected the fishery standardized CPUE trends in both regions.

## 4. Recruitment

The numbers of recruits to the model size groups under all scenarios have fluctuated in both EAG and WAG. For EAG, the model recruitment was high in 1987, 1988, 2008, 2015, 2017, and highest in 2014; and lowest in 1986. An increasing trend in recruitment was observed since the early-1990s in EAG. The model recruitment for WAG was high during 1983 to 1987 and highest in 2015; and lowest in 2011. After 1983 to 1987 peaks, the recruitment trend was low except the 2015 highest recruitment.

## 5. Management performance

The model was accepted at the September 2016 CPT and October 2016 SSC meetings for OFL determination for the 2017/18 fishery cycle. In addition, the CPT in January 2017 and SSC in February 2017 recommended using the Tier 3 method to compute OFL and ABC. The assessment model was first used for setting OFL and ABC for the 2017/18 fishing
season. The CPT in May 2017 and SSC in June 2017 accepted author's recommendation of using scenario 9 (i.e., model using the knife edge maturity to determine MMB) for OFL and ABC calculation. During the May 2017 meeting, the CPT noted that a single OFL and ABC are defined for Aleutian Islands golden king crab (AIGKC). However, separate models are available by area. Following last year's approach, we added OFLs and ABCs by area to calculate OFL and ABC for the entire stock. We could add them together without any modification because the stock status in the two areas after 2016/17 fishery was similar.

Among the six common scenarios for EAG and WAG, we recommend three scenarios (17_0 (base), 17_0d (three catchability and total selectivity), and 17_0e (McAllister and Ianelli method of re-weighting) for consideration and provide the status and catch specifications for the AIGKC stock. Scenario 17_0 is the base scenario with an updated $M$ of $0.21 \mathrm{yr}^{-1}$ and the addition of 2016/17 data. The model formulation is the same as that was accepted in 2017. Scenario 17_0d fits the recent three years' CPUE indices well for EAG, but the OFL and ABC are very low among the three selected scenarios. Scenario 17_0e is an alternative to the base scenario with McAllister and Ianelli method of size composition data weighting instead of Francis' method of reweighting. The OFL and ABC differences between 17_0e and 17_0 are small. The rest of the scenarios have some shortcomings either on adequacy of data or on model diagnostics; hence, are not considered. All scenarios assume the knife-edge maturity selection.

Status and catch specifications (1000 t) of Aleutian Islands golden king crab

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch $^{\mathbf{a}}$ | OFL | ABC $^{\mathbf{b}}$ |

| $2018 / 19^{\text {e }}$ | 6.107 | 17.793 |  |  |  | 5.581 | 4.186 |

a. Total retained catch plus estimated bycatch mortality of discarded bycatch during crab fisheries and groundfish fisheries.
b. $25 \%$ buffer was applied to total catch OFL to determine ABC.
c. 17_0 base scenario with Francis method of re-weighting
d. $17 \_0 d$ three catchability and total selectivity scenario with Francis method of reweighting
e. $\quad 17$ _0e McAllister and Ianelli method of re-weighting

Status and catch specifications (million lb) of Aleutian Islands golden king crab

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch $^{\mathbf{a}}$ | OFL | ABC $^{\mathbf{b}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2013 / 14$ | N/A | N/A | 6.290 | 6.38 | 7.038 | 12.54 | 11.28 |
| $2014 / 15$ | N/A | N/A | 6.290 | 6.11 | 6.807 | 12.53 | 9.40 |
| $2015 / 16$ | N/A | N/A | 6.290 | 6.016 | 6.782 | 12.53 | 9.40 |
| $2016 / 17$ | N/A | N/A | 5.545 | 5.716 | 6.497 | 12.53 | 9.40 |
| $2017 / 18$ | 13.325 | 31.315 | 5.545 | 5.699 | 6.487 | 13.333 | 10.000 |
| $2018 / 19^{\text {c }}$ | 13.329 | 39.577 |  |  |  | 12.157 | 9.118 |
| $2018 / 19^{\text {d }}$ | 13.002 | 32.331 |  |  |  | 8.737 | 6.553 |
| $2018 / 19^{\text {e }}$ | 13.464 | 39.227 |  |  |  | 12.305 | 9.228 |

a. Total retained catch plus estimated bycatch mortality of discarded bycatch during crab fisheries and groundfish fisheries.
b. $25 \%$ buffer was applied to total catch OFL to determine ABC.
c. 17_0 base scenario with Francis method of re-weighting
d. 17_0d three catchability and total selectivity scenario with Francis method of reweighting
e. 17_0e McAllister and Ianelli method of re-weighting

Since the $2017 / 18$ total catch of $2,942 \mathbf{t}(6.487$ million lb$)$ is below the OFL catch of $\mathbf{6 , 0 4 8} \mathbf{t}$ ( 13.333 million lb), "overfishing" did not occur in the Aleutian Islands golden king crab fishery in 2017/18.

## 6. Basis for the OFL

The length-based model developed for the Tier 3 analysis estimated MMB on February 15 each year for the period 1986 through 2016 and projected to February 15, 2018 for OFL and ABC determination. The Tier 3 approach uses a constant annual natural mortality $(M)$ and the mean number of recruits for the period 1987 - 2012 for OFL and ABC calculation. An $M$ of $0.21 \mathrm{yr}^{-1}$ derived from the combined data was used.

We provide the OFL and ABC estimates for EAG, WAG, and the two regions pooled together (i.e., for the entire Aleutian Islands, AI) for seven scenarios [17_0, 17_0a, 17_0b, 17_0c, 17_0d, 17_0e, and 17_0f (the last is only for EAG)] in the following six tables. As per September 2017 CPT suggestion, we also provide estimates for May 2017 CPT accepted scenario 9 (modified as $9 * *$ for WAG) in these tables. We treat scenario $17 \_0$ as the base scenario for EAG and WAG. We provide three options of OFL and ABC estimates based on scenarios 17_0, 17_0d, and 17_0e for CPT consideration and selection. Since the OFL and ABC have been set for the entire AI before, we suggest implementing the combined OFL and ABC for AI.

## 7. Probability density functions of the OFL

Assuming a lognormal distribution of total OFL, we determined the cumulative distributions of OFL and selected the median as the OFL.
8. Basis for the $A B C$ recommendation

An $\mathrm{x} \%$ buffer on the OFL; i.e., $\mathrm{ABC}=(1.0-\mathrm{x} / 100) * \mathrm{OFL}$. We considered $\mathrm{x}=25 \%$.

See also the section G on ABC.
9. A summary of the results of any rebuilding analysis:

Not applicable.

## A. Summary of Major Changes

1. Changes (if any) to management of the fishery

- In 2017, proposed changes to OFL and ABC calculation under model-based Tier 3 assessment were accepted.

2. Changes to input data

- Commercial fisheries data were updated with values from the most recent ADF\&G Area Management report (Leon et al., 2017) and most recent fish ticket data. Fishery data has been updated with the catches during 2016/17: retained catch for the directed fishery and discarded catch estimates for the directed fishery, non-directed crab fisheries, and groundfish fisheries. Thus the time series of data used in the model are: retained catch (1981/82-2016/17), total catch (1990/91-2016/17), and groundfish bycatch (1989/90-2016/17) biomass and size compositions.
- Fish ticket retained CPUE were standardized by the GLM with the lognormal link function for the 1985/86-1998/98 period.
- Observer pot sample legal size crab CPUE data were standardized by the generalized linear model (GLM) with the negative binomial link function with variable selection by R square criterion and CAIC (modified AIC), separately for 1995/96-2004/05 and 2005/06-2015/16 periods.
- For scenario 17_0a, observer data were standardized by VAST. The work is still preliminary.
- For scenario 17_0f for EAG, independent pot survey data from 2015 to 2017 were standardized by GLM and a likelihood component with this set of indices was added.
- Chela height with carapace length data from ADFG (1991) and NMFS (1984) surveys were analyzed outside the assessment model to determine the knife-edge maturity for mature male biomass calculation.

## 3. Changes to assessment methodology

- The equilibrium initial population and Tier $3 M M B_{M S Y}$ reference point estimation procedures used the mean number of recruits for 1987-2012.
- Francis re-weighting method was used to update the input effective sample sizes for length composition data for most scenarios, including $M$ profiling and retrospective analysis except scenario 17_0e in which we applied the McAllister and Ianelli reweighting method (McAllister and Ianelli, 1997; Siddeek et al. 2016c, 2017).
- We also added a stock projection part (Appendix F) to assess the viability of the stock under Tier 3 OFL and ABC control rule and a dynamic B0 analysis part (Appendix $\mathrm{H})$ to assess the biomass dynamics under no fishery.

## 4. Changes to assessment results

Expectedly, addition of one more year data changed the OFL and ABC estimates, but no dramatic changes were observed.

## B. Response to September 2017 CPT comments

Comment 1: The CPT recommended moving forward with the modeling convention adopted by the Groundfish Plan Teams. Naming conventions in groundfish SAFE guidelines: When a model constituting a "major change" from the original version of the base model is introduced, it is given a label of the form "Model $y y . j$," where $y y$ is the year (designated by the last two digits) that the model was introduced, and $j$ is an integer distinguishing this particular "major change" model from other "major change" models introduced in the same year.

When a model constituting only a "minor change" from the original version of the base model is introduced, it is given a label of the form "Model $y y . j x$," where " $x$ " is a letter distinguishing this particular "minor change" model from other "minor change" models derived from the original version of the same base model.

The distinction between "major" and "minor" model changes is determined subjectively by the author on the basis of qualitative differences in model

Response:
We followed this naming convention in labeling model scenarios: $17 \_0$ refers to model was established in 2017 and carried forward to 2018; no major changes occurred in 2018 and remain at the 0 -level. 17_0a refers to a minor change to 17_0; for example, CPUE indices were determined by spatio-temporal delta generalized linear mixed model (deltaGLMM) instead of GLM in this case.

## Comment 2: a) Reconsider what crabs are mature vs immature via breakpoint analysis; b)

 Repeat the breakpoint analysis using $\log (\mathrm{CH} / \mathrm{CL})$ vs CL , rather than the $\log \mathrm{CH}$ vs. $\log \mathrm{CL}$; c ) Because it was based on an inappropriate analysis, there is no need to show models with a logistic maturity curve, unless an improved approach can be found.Response:
As suggested by Steve Martel, we used the $\log (\mathrm{CH} / \mathrm{CL})$ vs. CL plot to get a better delineation of points for breakpoint analysis (see Appendix C figures). We used the breakpoint $50 \%$ maturity length for maturity determination in all scenarios. Sizes $\geq 111 \mathrm{~mm}$ CL were treated as mature and below this breakpoint immature.

## Comment 3: It is appropriate to use only the equilibrium abundance as a starting point.

Response:
We used the equilibrium starting point in 1960 in all scenarios.

## Comment 4: Moving forward, do not look at the core data.

Response:
We are not using the core data, but we have analyzed the independent pot survey data to estimate CPUE indices and incorporated them in a separate model scenario (17_0f). In the future we intend to use a spatio-temporal model to analyze the independent pot survey data.

## Comment 5: Continue analysis of spatio-temporal variation of the fishery using a program

 like VAST.
## Response:

We did a preliminary analysis of observer data using a spatio-temporal deltaGLMM (VAST, Thorson et al. 2015) and estimated an additional set of CPUE indices (see Appendix B) for scenario 17_0a. VAST requires spatially explicit catch data and some measure of 'area fished'. This type of information is available from the observer data, which include soak time, lat. and long., and depth. The necessary data for a spatio-temporal detlaGLMM are not available from dock side sampling; therefore, observer data are more suitable (see West coast SSC's March 2017 groundfish subcommittee report on the review of assessment methodologies proposed for use in 2017 groundfish assessments).

However, unlike the open West Coast Sea or Bering Sea, the Aleutian Islands areas provide additional constraints for spatial analysis due to the edge effects from the many islands. More work is needed to improve the use of spatio-temporal models in this region.

## Comment 6: Show a scenario with the McAllister and Ianelli re-weighting for comparison when choosing preferred model.

Response:
We provide scenario 17_0e, which considers McAllister and Ianelli method of re-weighting (see Appendix D for detail).

## Comment 7: Consider interaction terms, specifically area $x$ year interaction for CPUE standardization.

Response:
We standardized the CPUE considering the year: area interaction for scenario 17_0c (see Appendix B for details). The problem with this interaction analysis is that a lot of NAs occurred for many missing factor levels over the years. Anyway, we used the resulting CPUE indices in scenario 17_0c.

Comment 8: Consider scenarios with catchability and/or total selectivity breaking at a third point in 2010 (or a better year).

Response:
We considered scenario 17_0d with different sets of catchability and total selectivity for 1985/86-2004/05; 2005/06-2012/13; and 2013/14-2016/17.

Comment 9: Provide a comparison between the previous CPUE standardization and any new standardization methods that are applied.

Response:

Figure Comm.9. Comparison between May 2017 and May 2018 CPUE indices (top: WAG, bottom: EAG). In 2017 we categorized the area broadly into 10 longitudinally separated regions whereas in 2018 we used individual ADFG coded statistical area. The confidence intervals are $+/-2$ SE. Model estimated additional standard error was added to each input standard error.

## Comment 10: Include last year's model as a scenario for consideration.

Response:
We have included last year's model as scenario May17Sc9 to reflect scenario 9 with knife-edge maturity selectivity, which was accepted last year.

Comment 11: Overall model recommendation for May 2018: base model from last year (equilibrium initial abundance, knife edge maturity, both CPUE analyses with any significant interaction terms).

Response:
Done.

Response to October 2017 SSC comments
Comment 1: The SSC appreciates the CPT's consideration of model number convention and their recommendation to move forward with the modelling convention adopted by the Groundfish Plan Teams.

Response:
Done.

Comment 2: Although the use of chela height-carapace size regression lines has been validated for Chionoecetes crabs (snow, Tanner), the SSC expressed concern that the use of this approach to determine maturity may not be appropriate for lithodid (king) crabs. The SSC recommends that efforts be made to verify this relationship in lab or field experiments, as well as to review the available literature and application of this approach for other non-Chionoecetes species.

Response:
After analyzing a number of lithodid (king) crab stocks for size at maturity, Somerton and Otto (1986) observed that golden king crab provided a better separation of chela height growth at the onset of maturity than either red or blue king crabs (see Appendix C). We have also provided a literature review on king crab maturity determination in Appendix C, which supports the breakpoint type of analysis for male $50 \%$ maturity determination.

Comment 3: The SSC supports the exploration of the VAST geospatial model for investigation of fishery catch rate data, but cautions that the nonrandom nature of fisheries data adds an additional challenge to the standard assumptions of independence between the underlying density and the process of observation beyond that of standard statistically-designed survey programs.

Response:
We did a preliminary run of VAST for observer CPUE standardization and described its advantage and limitation (see response to CPT comment 5).

Comment 4: The SSC encourages the author to explore observer data and to discuss with the participants in the fishery potential changes in fisher behavior that may influence the relationship between fishery catch rates and crab abundance.

Response:
This is an ongoing process. We continue to explore this with the industry input and external experts.

Comment 5:The SSC reiterates previous concerns that this stock assessment relies solely on fishery data, and therefore carries a higher degree of uncertainty than other model-based assessments for crab stocks. The SSC encourages recent and future efforts by the industry to include survey pots in their fishing activity in order to generate additional data to inform this analysis. The SSC extends its appreciation to the industry for their generous cooperative research efforts on this important crab stock.

Response:
We recognized the higher degree of uncertainty in the assessment and therefore set the ABC using $25 \%$ buffer level. For the first time, we used the independent pot survey data in the model even though the time series is short (2015 to 2017).

## C. Introduction

1. Scientific name:

Golden king crab, Lithodes aequispinus J.E. Benedict, 1895.

## 2. Distribution:

General distribution of golden king crab is summarized by NMFS (2004). Golden king crab, also called brown king crab, occur from the Japan Sea to the northern Bering Sea (ca. $61^{\circ} \mathrm{N}$ latitude), around the Aleutian Islands, generally in high-relief habitat such as inter-island passes, on various sea mounts, and as far south as northern British Columbia (Alice Arm) (Jewett et al. 1985). They are typically found on the continental slope at depths of $300-1,000 \mathrm{~m}$ on extremely rough bottom. They are frequently found on coral bottom.

The Aleutian Islands king crab stock boundary is defined by the boundaries of the Aleutian Islands king crab Registration Area O (Figure 2). In this chapter, "Aleutian Islands Area" means the area described by the current definition of Aleutian Islands king crab Registration Area O. Leon et al. (2017) define the boundaries of Aleutian Islands king crab Registration Area O:

The Aleutian Islands king crab management area's eastern boundary is the longitude of Scotch Cap Light ( $164^{\circ} 44.72^{\prime} W$ long), the northern boundary is a line from Cape Sarichef ( $54^{\circ} 36^{\prime} \mathrm{N}$ lat) to $171^{\circ} \mathrm{W}$ long, north to $55^{\circ} 30^{\prime} \mathrm{N}$ lat, and the western boundary the Maritime Boundary Agreement Line as described in the Maritime Boundary Agreement between the United States and the Union of Soviet Socialist Republics signed in Washington, June 1, 1990 (Figure 1-1 in Leon et al. 2017). Area O encompasses
territorial waters of the state of Alaska (0-3 nautical miles) and waters of the Exclusive Economic Zone (3-200 nautical miles).

During 1984/85-1995/96, the Aleutian Islands king crab populations had been managed using the Adak and Dutch Harbor Registration Areas, which were divided at $171^{\circ} \mathrm{W}$ longitude (Figure 3), but from the 1996/97 season to present the fishery has been managed using a division at $174^{\circ} \mathrm{W}$ longitude (Figure 2). In March 1996 the Alaska Board of Fisheries (BOF) replaced the Adak and Dutch Harbor areas with the newly created Aleutian Islands Registration Area O and directed the Alaska Department of Fish and Game (ADF\&G) to manage the golden king crab fishery in the areas east and west of $174^{\circ} \mathrm{W}$ longitude as two distinct stocks. That re-designation of management areas was intended to more accurately reflect golden king crab stock distribution, coherent with the longitudinal pattern in fishery production prior to 1996/97 (Figure 4). The longitudinal pattern in fishery production relative to $174^{\circ} \mathrm{W}$ longitude since 1996/97 is similar to that observed prior to the change in management area definition, although there have been some changes in the longitudinal pattern in fishery production within the areas east and west of $174^{\circ} \mathrm{W}$ longitude (Figure 5).

Commercial fishing for golden king crab in the Aleutian Islands Area typically occurs at depths of 100-275 fathoms (183-503 m). Pots sampled by at-sea fishery observers in 2013/14 were fished at an average depth of 176 fathoms ( $322 \mathrm{~m} ; \mathrm{N}=499$ ) in the area east of $174^{\circ} \mathrm{W}$ longitude and 158 fathoms ( $289 \mathrm{~m} ; \mathrm{N}=1,223$ ) for the area west of $174^{\circ} \mathrm{W}$ longitude (Gaeuman 2014).

## 3. Evidence of stock structure:

Given the expansiveness of the Aleutian Islands Area and the existence of deep ( $>1,000$ m ) canyons between some islands, at least some weak structuring of the stock within the area would be expected. Data for making inferences on stock structure of golden king crab within the Aleutian Islands are largely limited to the geographic distribution of commercial fishery catch and effort. Catch data by statistical area from fish tickets and catch data by location from pots sampled by observers suggest that habitat for legal-sized males may be continuous throughout the waters adjacent to the islands in the Aleutian chain. However, regions of low fishery catch suggest that availability of suitable habitat, in which golden king crab are present at only low densities, may vary longitudinally. Catch has been low in the fishery in the area between $174^{\circ} \mathrm{W}$ longitude and $176^{\circ} \mathrm{W}$ longitude (the Adak Island area, Figures 4 and 5) in comparison to adjacent areas, a pattern that is consistent with low CPUE for golden king crab between $174^{\circ} \mathrm{W}$ longitude and $176^{\circ} \mathrm{W}$ longitude (Figure 6) during the 2002, 2004, 2006, 2010, and 2012 NMFS Aleutian Islands bottom trawl surveys (von Szalay et al. 2011). In addition to longitudinal variation in density, there is also a gap in fishery catch and effort between the Petrel Bank-Petrel Spur area and the Bowers Bank area; both of those areas, which are separated by Bowers Canyon, have reported effort and catch. Recoveries during commercial fisheries of golden king crab tagged during ADF\&G surveys (Blau and Pengilly 1994; Blau et al. 1998; Watson and Gish 2002; Watson 2004, 2007) provided no evidence of substantial movements by crab in the size classes that were tagged (males and females $\geq 90-\mathrm{mm}$ carapace length [CL]). Maximum straight-line distance between
release and recovery location of 90 golden king crab released prior to the 1991/92 fishery and recovered through the 1992/93 fishery was 61.2 km (Blau and Pengilly 1994). Of the 4,567 recoveries reported through 12 April 2016 for the male and female golden king crab tagged and released between $170.5^{\circ} \mathrm{W}$ longitude and $171.5^{\circ} \mathrm{W}$ longitude during the 1991, 1997, 2000, 2003, and 2006 ADF\&G Aleutian Island golden king pot surveys, none of the 3,807 with recovery locations specified by latitude and longitude were recovered west of $173^{\circ} \mathrm{W}$ longitude and only fifteen were recovered west of $172^{\circ} \mathrm{W}$ longitude (V. Vanek, ADF\&G, Kodiak, pers. comm.). Similarly, of 139 recoveries in which only the statistical area of recovery was reported, none were recovered in statistical areas west of $173^{\circ} \mathrm{W}$ longitude and only one was in a statistical area west of $172^{\circ} \mathrm{W}$ longitude.

## 4. Life history characteristics relevant to management:

There is a paucity of information on golden king crab life history characteristics due in part to the deep depth distribution ( $\sim 200-1000 \mathrm{~m}$ ) and the asynchronous nature of life history events (Otto and Cummiskey 1985; Somerton and Otto 1986). The reproductive cycle is thought to last approximately 24 months and at any one time, ovigerous females can be found carrying egg clutches in highly disparate developmental states (Otto and Cummiskey 1985). Females carry large, yolk-rich, eggs, which hatch into lecithotrophic (i.e., the larvae can develop successfully to juvenile crab without eating; Shirley and Zhou 1997) larvae that are negatively phototactic (Adams and Paul 1999). Molting and mating are also asynchronous and protracted (Otto and Cummiskey 1985; Shirley and Zhou 1997) with some indications of seasonality (Hiramoto 1985). Molt increment for large males (adults) in Southeast Alaska is 16.3 mm CL per molt (Koeneman and Buchanan 1985), and was estimated at 14.4 mm CL for legal males in the EAG (Watson et al. 2002). Annual molting probability of males decreases with increasing size, which results in a protracted inter-molt period and creates difficulty in determining annual molt probability (Watson et al. 2002). Male size-at-maturity varies among stocks (Webb 2014) and declines with increasing latitude from about 130 mm CL in the Aleutian Islands to 90 mm CL in Saint Matthew Island section (Somerton and Otto 1986). Along with a lack of annual survey data, limited stock-specific life history stock information prevents development of the standard length-based assessment model.

## 5. Brief summary of management history:

A complete summary of the management history through 2015/16 is provided in Leon et al. (2017, pages 9-14). The first commercial landing of golden king crab in the Aleutian Islands was in 1975/76, but directed fishing did not occur until 1981/82.

The Aleutian Islands golden king crab fishery was restructured beginning in 1996/97 to replace the Adak and Dutch Harbor areas with the newly created Aleutian Islands Registration Area O and golden king crab in the areas east and west of $174^{\circ} \mathrm{W}$ longitude were managed separately as two stocks (ADF\&G 2002). Hereafter, the east of $174^{\circ} \mathrm{W}$ longitude stock segment is referred to as EAG and the west of $174^{\circ} \mathrm{W}$ longitude stock segment is referred to as WAG. Table 1 provides the historical summary of number of vessels, GHL/TAC, harvest, effort, CPUE and average weight in the Aleutian Islands golden king crab fishery.

The fisheries in 1996/97-1997/98 were managed with 1,452 t (3,200,000 lb) for EAG and $1,225 \mathrm{t}(2,700,000 \mathrm{lb})$ for WAG (Table 1). During 1998/99-2004/05 the fisheries were managed with $1,361 \mathrm{t}(3,000,000 \mathrm{lb})$ for EAG and $1,225 \mathrm{t}(2,700,000 \mathrm{lb})$ for WAG. During 2005/06-2007/08 the fisheries were managed with a total allowable catch (TAC) of $1,361 \mathrm{t}(3,000,000 \mathrm{lb})$ for EAG and a TAC of $1,225 \mathrm{t}(2,700,000 \mathrm{lb})$ for WAG. By state regulation (5 AAC 34.612), TAC for the Aleutian Islands golden king crab fishery during 2008/09-2011/12 was $1,429 \mathrm{t}(3,150,000 \mathrm{lb})$ for EAG and $1,286 \mathrm{t}(2,835,000 \mathrm{lb})$ for WAG. In March 2012 the BOF changed 5 AAC 34.612 so that the TAC beginning in $2012 / 13$ would be $1,501 \mathrm{t}(3,310,000 \mathrm{lb})$ for the EAG and $1,352 \mathrm{t}(2,980,000 \mathrm{lb})$ for WAG. Additionally, the BOF added a provision to 5 AAC 34.612 that allows ADF\&G to lower the TAC below the specified level if conservation concerns arise. The TAC for $2016 / 17$ (and 2017/18) was reduced by $25 \%$ for WAG with $1,014 \mathrm{t}(2,235,000 \mathrm{lb})$ while keeping the TAC for EAG at the same level as that in the previous season.

During 1996/97-2016/17 the annual retained catch during commercial fishing (including cost-recovery fishing that occurred during 2013/14-2016/17) has averaged $2 \%$ below the annual GHL/TACs. During 1996/97-2016/17, the retained catch has been as much as $13 \%$ below (1998/99) and as much as $6 \%$ above (2000/01) the GHL/TAC.

A summary of other relevant SOA fishery regulations and management actions pertaining to the Aleutian Islands golden king crab fishery is provided below:

Beginning in 2005/06 the Aleutian Islands golden king crab fishery has been prosecuted under the Crab Rationalization Program. Accompanying the implementation of the Crab Rationalization program was implementation of a community development quota (CDQ) fishery for golden king crab in the eastern Aleutians (i.e., EAG) and the Adak Community Allocation (ACA) fishery for golden king crab in the western Aleutians (i.e., WAG; Hartill 2012). The CDQ fishery in the eastern Aleutians is allocated $10 \%$ of the golden king crab TAC for the area east of $174^{\circ} \mathrm{W}$ longitude and the ACA fishery in the western Aleutians is allocated $10 \%$ of the golden king crab TAC for the area west of $174^{\circ}$ W longitude. The CDQ fishery and the ACA fishery are managed by ADF\&G and prosecuted concurrently with the IFQ fishery.

Golden king crab may be commercially fished only with king crab pots (defined in 5 AAC 34.050). Pots used to fish for golden king crab in the Aleutian Islands Area must be operated from a shellfish longline and, since 1996, must have at least four escape rings of five and one-half inches minimum inside diameter installed on the vertical plane or at least one-third of one vertical surface of the pot composed of not less than nine-inch stretched mesh webbing to permit escapement of undersized golden king crab (5 AAC 34.625 (b)). Prior to the regulation requiring an escape mechanism on pots, some participants in the Aleutian Islands golden king crab fishery voluntarily sewed escape rings (typically 139 mm or 5.5 inches) into their gear or, more rarely, included panels with escape mesh (Beers 1992). With regard to the gear used since the establishment of 5 AAC 34.625 (b) in 1996, Linda Kozak, a representative of the industry, reported in a 19 September 2008 email to the Crab Plan Team that, "... the golden king crab fleet has
modified their gear to allow for small crab sorting," and provided a written statement from Lance Nylander, of Dungeness Gear Works in Seattle, who "believes he makes all the gear for the golden king crab harvesting fleet," saying that, "Since 1999, DGW has installed $9[-\mathrm{inch}]$ escape web on the door of over $95 \%$ of Golden Crab pot orders we manufactured." A study to estimate the contact-selection curve for male golden king crab that was conducted aboard one vessel commercial fishing for golden king crab during the 2012/13 season showed that gear and fishing practices used by that vessel were highly effective in reducing bycatch of sublegal-sized males and females (Vanek et al. 2013). In March 2011 (effective for 2011/12), the BOF amended 5 AAC 34.625 (b) to relax the "biotwine" specification for pots used in the Aleutian Islands golden king crab fishery relative to the requirement in 5 AAC 39.145 that "(1) a sidewall ...of all shellfish and bottomfish pots must contain an opening equal to or exceeding 18 inches in length... The opening must be laced, sewn, or secured together by a single length of untreated, 100 percent cotton twine, no larger than 30 thread." Regulation 5 AAC 34.625 (b)(1) allows the opening described in 5 AAC 39.145 (1) to be "laced, sewn, or secured together by a single length of untreated, 100 percent cotton twine, no larger than 60 [rather than 30] thread."

Regulation (5 AAC 34.610 (b)) sets the commercial fishing season for golden king crab in the Aleutian Islands Area as 1 August through 30 April. That regulatory fishing season became effective in 2015/16 (the commercial fishing season was set in regulation as 15 August through 15 May during 2005/06-2014/15).

Current regulations (5 AAC 39.645 (d)(4)(A)) stipulate that onboard observers are required on catcher vessels during the time that at least $50 \%$ of the retained catch is captured in each of the three trimesters of the 9 -month fishing season. Onboard observers are required on catcher-processors at all times during the fishing season.

Additional management measures include only males of a minimum size may be retained by the commercial golden king crab fishery in the Aleutian Islands Area. By SOA regulation (5 AAC 34.620 (b)), the minimum legal size limit is 6.0 -inches ( 152.4 mm ) carapace width (CW), including spines, which is at least one annual molt increment larger than the $50 \%$ maturity length of 120.8 mm CL for males estimated by Otto and Cummiskey (1985). A carapace length (CL) $\geq 136 \mathrm{~mm}$ is used to identify legal-size males when CW measurements are not available (Table 3-5 in NPFMC 2007b). Note that size limit for golden king crab has been 6 -inches ( 152.4 mm ) CW for the entire Aleutian Islands Area since the 1985/86 season. Prior to the 1985/86 season, the legal size limit was 6.5 -inches ( 165.1 mm ) CW for at least one of the now-defunct Adak or Dutch Harbor Registration Areas.

We re-evaluated the male maturity size using 1991 pot survey measurements of carapace length and chela height in EAG and 1984 NMFS measurements in WAG (Appendix C). Bootstrap analysis of chela height and carapace length data provided the median $50 \%$ male maturity length estimates of 107.02 mm CL in EAG and 107.85 mm CL in WAG. We used a knife-edge $50 \%$ maturity length of 111.0 mm CL, which is the lower limit of the next upper size bin, for mature male biomass (MMB) estimation.

Daily catch and catch-per-unit effort (CPUE) are determined in-season to monitor fishery performance and progress towards the respective TACs. Figures 7 to 9 provide the 1985/86-2016/17 time series of catches, CPUE, and the geographic distribution of catch during the 2016/17 fishing season. Increases in CPUE were observed during the late 1990s through the early 2000s, and with the implementation of crab rationalization in 2005. This is likely due to changes in gear configurations in the late 1990s (crab fishermen, personal communication, July 1, 2008) and, after rationalization, to increased soak time (Siddeek et al. 2015), and decreased competition owing to the reduced number of vessels fishing. Decreased competition could allow crab vessels to target only the most productive fishing areas. Trends in fishery CPUE within the areas EAG and WAG generally paralleled each other during 1985/86-2010/11, but diverged during 2011/122016/17 (an increasing trend in EAG and a decreasing trend in WAG).
6. Brief description of the annual ADF\&G harvest strategy:

The annual TAC is set by state regulation, 5 AAC 34.612 (Harvest Levels for Golden King Crab in Registration Area O), as approved by the BOF in March 2012:
(a) Until the Aleutian Islands golden king crab stock assessment model and a state regulatory harvest strategy are established, the harvest levels for the Registration Area O golden king crab fishery are as follows:
(1) east of $174^{\circ} \mathrm{W}$ long. (EAG): 3.31 million pounds; and
(2) west of $174^{\circ} \mathrm{W}$ long. (WAG): 2.98 million pounds;
(b) The department may reduce the harvest levels based on the best scientific information available and considering the reliability of estimates and performance measures, sources of uncertainty as necessary to avoid overfishing, and any other factors necessary to be consistent with sustained yield principles.

In addition to the retained catch that is limited by the TAC established by ADF\&G under 5 AAC 34.612, ADF\&G also has authority to annually receive receipts of $\$ 500,000$ through cost-recovery fishing on Aleutian Islands golden king crab. The retained catch from that cost-recovery fishing is not counted against attainment of the annuallyestablished TAC.
At the March 2018 meeting, The BOF decided to amend the phrase "may reduce to "may modify" in (b).
7. Summary of the history of the basis and estimates of $M M B_{M S Y}$ or proxy $M M B_{M S Y}$ : We estimated the proxy $M M B_{M S Y}$ as $M M B_{35 \%}$ using the Tier 3 estimation procedure, which is explained in a subsequent section.

## D. Data

1. Summary of new information:
(a) Commercial fishery retained catch by size, estimated total catch by size, groundfish male discard catch by size, observer CPUE index, commercial fishery CPUE index,
and tag-recapture data were updated to include 2016/17 information. The details are given in the pictorial table below.

2. Data presented as time series:
a. Total Catch:

Fish ticket data on retained catch weight, catch numbers, effort (pot lifts), CPUE, and average weight of retained catch for 1981/82-2016/17 (Table 1). Estimated total catch weight for 1990/91-2016/17 (Table 2a).
b. Bycatch and discards:

Retained catch, bycatch mortality (male and female of all sizes included) separated by the crab fishery and groundfish fishery, and total fishery mortality for 1981/822016/17 (Table 2). Crab fishery discards are available after observer sampling was established in 1988/89. Some observer data exists for the 1988/89-1989/90 seasons, but those data are not considered reliable. Table 2 provides crab fishery discards and groundfish fishery bycatch for 1991/92-2016/17 seasons.

## c. Catch-per-unit-effort:

- Pot fishery and observer nominal retained and total CPUE, pot fishery effort, observer sample size, and estimated observer CPUE index delineated by EAG and WAG for 1985/86-2016/17 (Table 3).
- Estimated commercial fishery CPUE index with coefficient of variation (Table 4 for EAG and Table 22 for WAG). The estimation methods, CPUE fits and diagnostic plots are described in Appendixes B and G.

## d. Catch-at-length:

Information on length compositions (Figures 11 to 13 for length compositions for EAG; and 29 to 31 for length compositions for WAG).
e. Survey biomass estimates:

They are not available for the area because no systematic surveys, covering the entire fishing area, have occurred.
f. Survey catch-at-length:

They are not available.
g. Other time series data: None.
3. Data which may be aggregated over time:

- Molt and size transition matrix: Tag release - recapture -time at liberty records from 1991, 1997, 2000, 2003, and 2006 male tag crab releases were aggregated by year at liberty to determine the molt increment and size transition matrix by the integrated model.
- Weight-at-length: Male length-weight relationship: $\mathrm{W}=\mathrm{aL}^{\mathrm{b}}$ where $\mathrm{a}=$ $3.7255^{*} 10^{-4}, \mathrm{~b}=3.0896$ (updated estimates).
- Natural mortality: Model estimated fixed natural mortality value was used in the assessment.

4. Information on any data sources that were available, but were excluded from the assessment:
Data from triennial ADF\&G pot surveys for Aleutian Islands golden king crab in a limited area in EAG (between $170^{\circ} 21^{\prime}$ and $171^{\circ} 33^{\prime} \mathrm{W}$ longitude) that were performed during 1997 (Blau et al. 1998), 2000 (Watson and Gish 2002), 2003 (Watson 2004), and 2006 (Watson 2007) are available, but were not used in this assessment. However, the tag release recapture data from these surveys were used.

## E. Analytic Approach

1. History of modeling approaches for this stock:

A size structured assessment model based on only fisheries data has been under development for several years for the EAG and WAG golden king crab stocks. The model was accepted in 2016 for OFL and ABC setting for the 2017/18 season. The CPT in January 2017 and SSC in February 2017 recommended to using the Tier 3 procedure to set the OFL and ABC. They also suggested to using the maturity data to estimate MMB. We followed these suggestions in this report. This is the second fishing season we are proposing to use the model-based OFL and ABC setting.

## 2. Model Description:

a. Description of overall modeling approach:

The underlying population dynamics model is male-only and length-based (Appendix A). This model combines commercial retained catch, total catch, groundfish fishery discarded catch, standardized observer legal size catch-per-unit-effort (CPUE) indices, fishery retained catch size composition, total catch size composition, and tag recaptures by release-recapture length to estimate stock assessment parameters. The tagging data were used to calculate the size transition matrix. To estimate the male mature biomass (MMB), we used the knife-edge $50 \%$ maturity based on the chela height and carapace length data analysis. To include a long time series of CPUE indices for stock abundance contrast, we also considered the 1985/86-1998/99 legal size standardized CPUE indices as a separate likelihood component in all scenarios (see Table T1). As a first attempt, we used VAST to estimate a separate set of observer CPUE indices for the model scenario 17_0a and also used the 2015-2017 fishery independent pot survey CPUE indices for the model scenario 17_Of.
There were significant changes in fishing practice due to changes in management regulations (e.g., constant TAC since 1996/97 and crab rationalization since 2005/06), pot configuration (escape web on the pot door increased to 9 -inch since 1999), and improved observer recording in Aleutian Islands golden king crab fisheries since 1998. These changes prompted us to consider two sets of catchability and total selectivity parameters with only one set of retention parameters for the periods 1985/86-2004/05 and 2005/06-2016/17. However, in order to respond to the September 2017 CPT comment, we considered three catchabilities, three sets of total selectivity, and one set of retention curves in one scenario (scenario 17_0d).

We fitted the observer and commercial fishery CPUE indices with estimated (by GLM or VAST) standard errors and an additional model estimated constant variance. The assessment model predicted total and retained CPUEs. However, we compared only the predicted retained CPUE with the observer legal size crab CPUE indices in the likelihood function because observer recordings of legal size crabs are reliable.

The data series ranges used for the WAG are the same as those for EAG.
b. Software:

AD Model Builder (Fournier et al. 2012).
c.-f. Details are given in Appendix A.
g. Critical assumptions and consequences of assumption failures:

Because of the lack of an annual stock survey, we relied heavily on standardized CPUE indices (Appendix B) and catch and size composition information to determine the stock abundance trends in both regions. We assumed that the observer and fish ticket CPUE indices are linearly related to exploitable abundance. We kept $M$ constant at $0.21 \mathrm{yr}^{-1}$. The $M$ value was the combined estimates for EAG and WAG (Figure 1). We assumed directed pot fishery discard mortality at $0.20 \mathrm{yr}^{-1}$, overall groundfish fishery mortality at $0.65 \mathrm{yr}^{-1}$ [mean of groundfish pot fishery mortality $\left(0.5 \mathrm{yr}^{-1}\right)$ and groundfish trawl fishery mortality $\left.\left(0.8 \mathrm{yr}^{-1}\right)\right]$, groundfish fishery selectivity at full selection for all length classes (selectivity $=1.0$ ). Any discard of
legal size males in the directed pot fishery was not considered in this analysis. These fixed values invariably reduced the number of model parameters to be estimated and helped in convergence. We assumed different $q$ 's (scaling parameter for standardized CPUE in the model, Equation A. 13 in Appendix A) and logistic selectivity patterns (Equation A. 9 in Appendix A) for different periods for the pot fishery.
h. Changes to any of the above since the previous assessment:

None.
i. Model code has been checked and validated.

The code is available from the authors.

## 3. Model Selection and Evaluation

a. Description of alternative model configurations:

We considered 7 scenarios for EAG and 6 scenarios for WAG (Table T1). We presented OFL and ABC results for all scenarios separately for EAG, WAG, and the entire AI in the executive summary tables. We considered scenario 17_0 as the base scenario. It considers:
i) Initial abundance by the equilibrium condition considering the mean number of recruits for 1987-2012: The equilibrium abundance was determined for 1960, projected forward with only $M$ and annual recruits until 1980, then retained catches removed during 1981-1984 and projected to obtain the initial abundance in 1985 (see Equations A. 4 and A. 5 in Appendix A).
ii) Observer CPUE indices for 1995/96-2016/17.
iii) Fishery CPUE indices for 1985/86-1998/99.
iv) Initial (Stage-1) weighting of effective sample sizes: number of vessel-days for retained and total catch size compositions, and number of fishing trips for groundfish discard size composition (the groundfish size composition was not used in the model fitting); and (Stage-2) iterative re-weighting of effective sample sizes by the Francis and McAllister and Ianelli methods (Appendix D).
v) Two catchability and two sets of logistic total selectivity for the periods 1985/862004/05 and 2005/06-2016/17, and a single set of logistic retention curve parameters.
vi) Full selectivity (selectivity $=1.0$ ) for groundfish (trawl) bycatch.
vii) Knife-edge $50 \%$ maturity size.
viii) Stock dynamics $M=0.21 \mathrm{yr}^{-1}$, pot fishery handling mortality $=0.2 \mathrm{yr}^{-1}$, and mean groundfish bycatch handling mortality $=0.65 \mathrm{yr}^{-1}$.
ix) Size transition matrix using tagging data estimated by the normal probability function with the logistic molt probability sub-model. The tag-recaptures were treated as Bernoulli trials (i.e., Stage-1 weighting).
x) The time period, 1987-2012, was used to determine the mean number of recruits for $M M B_{35 \%}$ (a proxy for $M M B_{M S Y}$ ) estimation under Tier 3.

The salient features and variations from the base scenario of all other scenarios are listed in Table T1. The list of fixed and estimable parameters are provided in Table A1 and
detail weights with coefficient of variations (CVs) assigned to each type of data are listed in Table A2 of Appendix A.

As per CPT and SSC requests, initial parameter values for scenario 17_0 were jittered to confirm model global convergence. The results indicated that global convergence was achieved for almost all the runs (Appendix E).

Table T1. Features of model scenarios. Initial condition was estimated by the equilibrium condition for all scenarios. Changes from scenario 17_0 specifications are highlighted by the light blue shade.

| Scenario | Sizecomposition weighting | Catchability and logistic total selectivity sets | Maturity | Standardized CPUE data type | Treatment of $M$ and Tier 3 $M_{M B} B_{M S Y}$ reference points | $\begin{gathered} \text { Natural } \\ \text { mortality }(M \\ \left.y r^{-1}\right) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0b | Stage1:Number of boat_days/trips Stage-2: Francis method | 2 | Knifeedge, 111 mm CL | Observer from 1995/96-2016/17 \& Fish Ticket from 1985/86-1998/99; <br> GLM variable selection by R square criterion | Estimate a common $M$ using the combined EAG and WAG data without an $M$ prior | $0.2254 ;$ Individual component's estimate: EAG: 0.2142 WAG: 0.2142 |
| 17_0 | Stage1:Number of boat_days/trips Stage-2: Francis method | 2 | $\begin{gathered} \text { Knife- } \\ \text { edge, } 111 \\ \text { mm CL } \end{gathered}$ | Observer from 1995/96-2016/17 \& Fish Ticket from 1985/86-1998/99; GLM variable selection by R square criterion | Single $M$ from combined EAG and WAG data; Tier $3 M M B_{M S Y}$ reference points based on average recruitment from 1987-2012 | 0.21 |
| 17_0a | Stage1:Number of boat_days/trips Stage-2: Francis method | 2 | Knifeedge, 111 mm CL | Observer CPUE by VAST \& Fish Ticket CPUE by GLM; GLM variable selection by R square criterion | Single $M$ from combined EAG and WAG data; Tier $3 M M B_{M S Y}$ reference points based on average recruitment from 1987-2012 | 0.21 |

## b. Progression of results:

The OFL and ABC estimates are similar to those estimated by the 2017 model.
c. Label the approved model from the previous year as model 0:

Following the September CPT suggestion we used the notation 17_0 for the base model which came from the previous assessment.
d. Evidence of search for balance between realistic and simpler models:

Unlike annually surveyed stocks, Aleutian Islands golden king crab stock biomass is difficult to track and several biological parameters are assumed based on knowledge from red king crab (e.g., handling mortality rate of $0.2 \mathrm{yr}^{-1}$ ) due to a lack of species/stock specific information. We fixed a number of model parameters after initially running the model with free parameters to reduce the number of parameters to be estimated (e.g., groundfish bycatch selectivity parameters were fixed). The seven scenarios also considered different configuration of parameters to select parsimonious models. The detailed results of the seven scenarios are provided in tables and figures. The total catch OFLs and the reduction in terminal (2016) MMB from the initial condition (i.e., virgin MMB in 1960) for all scenarios for EAG and WAG are provided in Table 38. We also included the results of the accepted 2017 model scenario, Sc9, in this table for comparison. The reduction in terminal MMB from the initial condition is higher for WAG than EAG.

## e. Convergence status and criteria:

ADMB default convergence criteria were used.
f. Table of the sample sizes assumed for the size compositional data:

We estimated the initial input effective sample sizes (i.e., Stage-1) either as number of vessel-days for retained and total catch compositions and number of fishing trips for groundfish size composition (note: we did not use the groundfish size composition in the model fit) for all scenarios. Then we estimated the Stage-2 effective sample sizes iteratively from Stage-1 input effective sample sizes using the Francis' (2011, 2017) mean length based method and McAllister and Ianelli method (McAllister and Ianelli, 1997) (Appendix D).

We provide the initial input sample sizes (Stage-1) and Stage-2 effective sample sizes for scenarios 17_0 to 17_0f in Tables 5 to 11 for EAG and Tables 23 to 28 for WAG.
g. Provide the basis for data weighting, including whether the input effective sample sizes are tuned and the survey CV adjusted:
Described previously (f) and details are in Appendix D.
h. Do parameter estimates make sense and are they credible?

The estimated parameter values are within the bounds and various plots suggest that the parameter values are reasonable for a fixed $M$ value for the golden king crab stocks.
i. Model selection criteria:

We used a number of diagnostic criteria to select the appropriate models for our recommendation: CPUE fits, observed vs. predicted tag recapture numbers by time at large and release size, retained and total catch, and groundfish bycatch fits. Figures are provided for all scenarios in the Results section.

## j. Residual analysis:

We illustrated residual fits by bubble plots for retained and total catch size composition predictions in various figures in the Results section.
k. Model evaluation:

Only one model with a number of scenarios is presented and the evaluations are presented in the Results section below.

## 4. Results

## 1. List of effective sample sizes and weighting factors:

The Stage-1 and Stage-2 effective sample sizes are listed for various scenarios in Tables 5 to 11 for EAG and Tables 23 to 28 for WAG. The weights for different data sets are provided in Table A2 for various scenarios, respectively, for EAG and WAG (Appendix A). These weights (with the corresponding coefficient of variations) adequately fitted the length compositions and no further changes were examined.

We used weighting factors for catch biomass, recruitment deviation, pot fishery F , and groundfish fishery F. We set the retained catch biomass to a large value (500.0) because retained catches are more reliable than any other data sets. We scaled the total catch biomass in accordance with the observer annual sample sizes with a maximum of 250.0. The total catches were derived from observer nominal total CPUE and effort. In some years, observer sample sizes were low (Tables 3). We chose a small groundfish bycatch weight (0.2) based on the September 2015 CPT suggestion to lower its weight. We used the best fit criteria to choose the lower weight for the groundfish bycatch. Groundfish bycatch of Aleutian Islands golden king crab is very low. We set the CPUE weights to 1.0 for all scenarios. We included a constant (model estimated) variance in addition to input CPUE variance for the CPUE fit. We used the Burnham et al. (1987) suggested formula for $\ln (\mathrm{CPUE})$ [and $\ln (\mathrm{MMB})$ ] variance estimation (Equation A. 14 of Appendix A). However, the estimated additional variance values were small for both observer and fish ticket CPUE indices for the two regions. Nevertheless, the CPUE index variances estimated from the negative binomial and lognormal GLMs were adequate to fit the model, as confirmed by the fit diagnostics (Fox and Weisberg 2011). Parameter estimates are provided in Tables 12 and 13 for EAG and 29 and 30 for WAG for all scenarios. The numbers of estimable parameters are listed in Table A1 of Appendix A. The weights with the corresponding coefficient of variations specifications are detailed in Tables A2 of Appendix A for EAG and WAG.

## 2. Include tables showing differences in likelihood:

Tables 21 and 37 list the total and component negative log likelihood values and their differences between scenarios of similar sample sizes and free parameters for EAG and WAG, respectively.

## 3. Tables of estimates:

a. The parameter estimates with coefficient of variation for all scenarios are summarized respectively in Tables 12 and 13 for EAG and 29 and 30 for WAG. We have also provided the boundaries for parameter searches in those tables. All parameter estimates were within the bounds.
b. All scenarios considered molt probability parameters in addition to the linear growth increment and normally distributed growth variability parameters to determine the size transition matrix.
c. The mature male and legal male abundance time series for all scenarios are summarized in Tables 14 to 20 for EAG and Tables 31 to 36 for WAG.
d. The recruitment estimates for those scenarios are summarized in Tables 14 to 20 for EAG and Tables 31 to 36 for WAG.
e. The negative log-likelihood component values and total negative log-likelihood values for all scenarios are summarized in Table 21 for EAG and Table 37 for WAG. Scenario 17_0d has the minimum total negative log likelihood for EAG whereas scenario 17_0e has the minimum for WAG. Among the scenarios with equal data components (base) and number of free parameters, scenario 17_0e has the lowest total negative log likelihoods for both EAG and WAG. Thus, we chose scenarios 17_0 (base), 17_0d, and 17_0e for OFL and ABC options for consideration.

## 4. Graphs of estimates:

## a. Selectivity:

Total selectivity and retention curves of the pre- and post-rationalization periods for all scenarios are illustrated in Figure 14 for EAG and Figure 32 for WAG. Total selectivity for the pre-rationalization period was used in the tagging model. The groundfish bycatch selectivity appeared flat in the preliminary analysis, indicating that all size groups were vulnerable to the gear. This is also shown in the size compositions of groundfish bycatch (Figures 13 and 31 for EAG and WAG, respectively). Thus, we set the groundfish bycatch selectivity to 1.0 for all length-classes in the subsequent analysis.

## b. Mature male biomass:

The mature male biomass time series for nine (a subset of 11) scenarios are depicted in Figures 28 and 46 for EAG and WAG, respectively. Mature male biomass tracked the CPUE trends well for all scenarios for EAG and WAG. The biomass variance was estimated using Burnham et al. (1987) suggested formula
(Equation A. 14 in Appendix A). We determined the mature male biomass values on 15 February each year and considered the 1987-2012 time series of recruits for estimating mean number of recruits for $M M B_{35 \%}$ calculation under Tier 3 approach.
c. Fishing mortality:

The full selection pot fishery F over time for all scenarios is shown in Figures 27 and 45 for EAG and WAG, respectively. The F peaked in late 1980s and early to mid-1990s and systematically declined in the EAG. On the other hand, the F in the WAG peaked in late 1980s, 1990s and early 2000s, then declined in late 2000s and slightly increased since 2010. The increase in F in recent years may be due to a decline in abundance under constant high harvest allocation to WAG.

## d. F vs. MMB:

We provide these plots for scenarios 17_0 and 17_0d for EAG and WAG in Figure 47.
e. Stock-Recruitment relationship: None.

## f. Recruitment:

The temporal changes in total number of recruits to the modeled population for all scenarios are illustrated in Figure 16 for EAG and in Figure 34 for WAG. The recruitment distribution to the model size group (101-185 mm CL) is shown in Figures 17 and 35 for EAG and WAG, respectively for all scenarios.

## 5. Evaluation of the fit to the data:

## g. Fits to catches:

The fishery retained, total, and groundfish bycatch (observed vs. estimated) plots for all scenarios are illustrated in Figures 19 and 37 for EAG and WAG, respectively. The 1981/82-1984//85 retained catch plots for all scenarios are depicted in Figures 20 and 38 for EAG and WAG, respectively. All predicted fits were very close to observed values, especially for retained catch and groundfish bycatch mortality. However, pre 1995 total catch data did not fit well.
h. Survey data plot:

We did not consider the pot survey data for the analysis.
i. CPUE index data:

The predicted vs. input CPUE indices for all scenarios are shown in Figure 26 for EAG and Figure 44 for WAG. Scenario 17_0d fit the recent three years’ CPUE indices well for EAG; on the other hand, scenario 17_0c did not fit the post rationalization period CPUE indices well for WAG. The CPUE variance was estimated using Burnham et al. (1987) suggested formula (Equation A. 14 in Appendix A).

## j. Tagging data:

The predicted vs. observed tag recaptures by length-class for years 1 to 6 recaptures are depicted in Figure 15 for EAG and Figure 33 for WAG. The predictions appear reasonable. Note that we used the EAG tagging information for size transition matrix estimation for both stocks (EAG and WAG). The size transition matrices estimated using EAG tagging data in the EAG and WAG models were similar.

## k. Molt probability:

The predicted molt probabilities vs. CL for all scenarios are depicted in Figures 18 and 36 for EAG and WAG, respectively. The fits appear to be satisfactory.

1. Fit to catch size compositions:

Retained, total, and groundfish discard length compositions are shown in Figures 11 to 13 for EAG and 29 to 31 for WAG. The retained and total catch size composition fits appear satisfactory. But, the fits to groundfish bycatch size compositions are bad. Note that we did not use the groundfish size composition in any of the model scenario fits.

We illustrate the standardized residual plots as bubble plots of size composition over time for retained catch (Figures 21 and 23 for EAG, and 39 and 41 for WAG) and for total catch (Figures 22 and 24 for EAG, and 40 and 42 for WAG) for two scenarios (17_0 and 17_0d). The retained catch bubble plots appear random for the selected scenarios.
m . Marginal distributions for the fits to the composition data:
We did not provide this plot in this report.
n. Plots of implied versus input effective sample sizes and time series of implied effective sample sizes:
We did not provide the plots, but provided the estimated values in Tables 5 to 11 for EAG and in Tables 23 to 28 for WAG, respectively.
o. Tables of RMSEs for the indices:

We did not provide this table in this report.
p. Quantile-quantile (Q-Q) plots:

We did not provide these plots for model fits in this report. However, we provided these plots in a separate Appendix F for CPUE standardization diagnostic.

## 6. Retrospective and historical analysis:

The retrospective fits for scenarios 17_0 and 17_0d are shown in Figure 25 for EAG and in Figure 43 for WAG. The retrospective fits were prepared for the whole time series 1961 to 2017. The retrospective patterns did not show severe departure when four terminal years' data were removed systematically, especially for WAG and
hence the current formulation of the model appears stable. The Mohn rho values are also given in the figures, which indicate no severe model misspecification (i.e., small rho) (Mohn, 1999; Deroba, 2014). A severe drop in modeled biomass from the initial MMB occurred when the fishery time series started in 1981.
7. Uncertainty and sensitivity analysis:

- The main task was to determine a plausible size transition matrix to project the population over time. In a previous study, we investigated the sensitivity of the model to determining the size transition matrix by using or not using a molt probability function (Siddeek et al. 2016a). The model fit is better when the molt probability model is included. Therefore, we included a molt probability submodel for the size transition matrix calculation in all scenarios.
- We also determined likelihood values at different $M$ and plotted component negative likelihood against $M$ (Figure 1).

## 8. Conduct 'jitter analysis':

We conducted the (random) jitter analysis on scenario 17_0 (base) model fitted parameters. This analysis indicated that the base model achieved the global convergence (details in Appendix E).

## F. Calculation of the OFL

## 1. Specification of the Tier level:

Aleutian Islands golden king crab has been elevated to Tier 3 level in 2017 for OFL and ABC determination. In the following section, we provide the method to determine OFL and ABC

## 2. List of parameter and stock size estimates (or best available proxies thereof) required by limit and target control rules specified in the fishery management plan:

The critical assumptions for $M M B B_{M S Y}$ reference point estimation are:
a. Natural mortality is constant.
b. Growth transition matrix is fixed and estimated using tagging data with the molt probability sub-model.
c. Total fishery selectivity and retention curves are length dependent and the 2005/062016/17 period selectivity estimates are used.
d. Groundfish bycatch fishery selectivity is kept constant at 1.0 for all length groups.
e. Model estimated recruits (in millions of crab) are averaged for the time period 19872012.
f. Model estimated groundfish bycatch mortality values are averaged for the period 2007/08 - 2016/17 (10 years).
g. A knife-edge $50 \%$ maturity size is used for MMB estimation.

## Method:

We simulated the population abundance starting from the model estimated terminal year stock size by length, model estimated parameter values, a fishing mortality value ( F ), and adding a constant number of annual recruits. Once the stock dynamics were stabilized (we used the $99^{\text {th }}$ year estimates) for an F , we calculated the $\mathrm{MMB} / \mathrm{R}$ for that F . We computed the relative $M M B / R$ in percentage, $\left(\frac{M M B}{R}\right)_{x \%}\left(\right.$ where $\mathrm{x} \%=\frac{\frac{M M B_{F}}{R}}{\frac{M M B_{0}}{R}} \times 100$ and $M M B_{0} / R$ is the virgin $\left.M M B / R\right)$ for different F values.
$F_{35 \%}$ is the F value that produces the $\mathrm{MMB} / \mathrm{R}$ value equal to $35 \%$ of $M M B_{0} / R$.
$M M B_{35 \%}$ is estimated using the following formula:
$M M B_{35 \%}=\left(\frac{M M B}{R}\right)_{35} \times \bar{R}$, where $\bar{R} \quad$ is the mean number of model estimated recruits for a selected period.

## 3. Specification of the OFL:

## a. Provide the equations (from Amendment 24) on which the OFL is to be based:

$F_{O F L}$ is determined using Equation A. 28 in Appendix A. The OFL is estimated by an iterative procedure accounting for intervening total removals (see Appendix A for the formulas).
b. Basis for projecting MMB to the time of mating:

We followed the NPFMC 2007a guideline.
c. Specification of Fofl, OFL, and other applicable measures (if any) relevant to determining whether the stock is overfished or if overfishing is occurring:
See Management Performance table, below. The OFL and ABC values for 2018/19 in the table below are the recommended values. The TACs for 2013/14-2015/16 in the table below do not include landings towards a cost-recovery fishery goal, but the catches towards cost-recovery fishing in 2013/14-2014/15 are included in the retained and total catch.

Status and catch specifications (1000t) of Aleutian Islands golden king crab

| Year | MSST | Biomass <br> (MMB) | TAC | Retained <br> Catch | Total <br> Catch $^{\mathbf{a}}$ | OFL | ABC $^{\mathbf{b}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2013 / 14$ | N/A | N/A | 2.853 | 2.894 | 3.192 | 5.69 | 5.12 |
| $2014 / 15$ | N/A | N/A | 2.853 | 2.771 | 3.088 | 5.69 | 4.26 |

a. Total retained catch plus estimated bycatch mortality of discarded bycatch during crab fisheries and groundfish fisheries.
b. $25 \%$ buffer was applied to total catch OFL to determine ABC.
c. 17_0 base scenario with Francis method of re-weighting
d. 17_0d three catchability and total selectivity scenario with Francis method of reweighting
e. 17_0e McAllister and Ianelli method of re-weighting

## 4. Specification of the retained portion of the total catch OFL:

The retained catch portion of the total-catch OFL for EAG, WAG, and the entire Aleutian Islands (AI) stock were calculated for the three recommended scenario options (17_0, 17_0d, and 17_0e):

Scenario 17_0:
EAG: $3,756 \mathrm{t}$ ( 8.280 million lb)
WAG: $1,473 \mathrm{t}$ ( 3.248 million lb)
AI: $\quad 5,229 \mathrm{t}$ ( 11.528 million lb).
Scenario 17_0d:
EAG: $2,355 \mathrm{t}$ ( 5.191 million lb)
WAG: $1,375 \mathrm{t}$ ( 3.031 million lb )
AI: $3,730 \mathrm{t}$ (8.222 million lb).
Scenario 17_0e:
EAG: $3,817 \mathrm{t}$ ( 8.415 million lb )
WAG: $1,484 \mathrm{t}$ ( 3.271 million lb)
AI: $\quad 5,301 \mathrm{t}(11.686$ million lb$)$.

## G. Calculation of ABC

1. We estimated the cumulative probability distribution of OFL assuming a $\log$ normal distribution of OFL. We calculated the OFL at the 0.5 probability and the maximum ABC at the 0.49 probability and considered additional buffer by setting $\mathrm{ABC}=0.75^{*} \mathrm{OFL}$
We provide the ABC estimates with the $25 \%$ buffer for EAG, WAG, and AI considering scenarios 17_0, 17_0d, and 17_0e:

Scenario 17_0:
EAG: $\mathrm{ABC}=2,938 \mathrm{t}(6.478$ million lb)
WAG: $\mathrm{ABC}=1,197 \mathrm{t}(2.640$ million lb$)$
$\mathrm{AI}: \mathrm{ABC}=4,136 \mathrm{t}$ (9.118 million lb).
Scenario 17_0d:
EAG: $\mathrm{ABC}=1,860 \mathrm{t}$ ( 4.102 million lb)
WAG: $\mathrm{ABC}=1,112 \mathrm{t}(2.451$ million lb$)$
$\mathrm{AI}: \mathrm{ABC}=2,972 \mathrm{t}$ (6.553 million lb).
Scenario 17_0e:
EAG: $\mathrm{ABC}=2,980 \mathrm{t}$ ( 6.570 million lb)
WAG: $\mathrm{ABC}=1,206 \mathrm{t}(2.658$ million lb$)$
AI: $\mathrm{ABC}=4,186 \mathrm{t}$ (9.228 million lb).

## 2. List of variables related to scientific uncertainty:

- Model relied largely on fisheries data.
- Observer and fisheries CPUE indices played a major role in the assessment model.
- Natural mortality was estimated in the model and independent estimate is not available.
- The time period to compute the average number of recruits (1987-2012) relative to the assumption that this represents "a time period determined to be representative of the production potential of the stock."
- Fixed bycatch mortality rates were used in each fishery (crab fishery and the groundfish fishery) that discarded golden king crab.
- Discarded catch and bycatch mortality for each fishery that bycatch occurred in during 1981/82-1989/90 were not available.

3. List of additional uncertainties for alternative sigma-b.

We recommended a large buffer of $25 \%$ to account for additional uncertainties.

## 4. Author recommended ABC :

Authors recommended three ABC options based on $25 \%$ buffer on the OFL under scenarios 17_0, 17_0d, and 17_0e.

## H. Rebuilding Analysis

Not applicable. This stock has not been declared overfished.

## I. Data Gaps and Research Priorities

1. The recruit abundances were estimated from commercial catch sampling data. The implicit assumption in the analysis was that the estimated recruits come solely from the same exploited stock through growth and mortality. The current analysis did not consider the possibility that additional recruitment may occur through immigration from neighboring areas and possibly separate sub-stocks. Extensive tagging experiments or resource surveys are needed to investigate stock distributions.
2. We estimated $M$ in the model. However, an independent estimate of $M$ is needed for comparison, which could be achieved with tagging experiments.
3. An extensive tagging study will also provide independent estimates of molting probability and growth. We used the historical tagging data to determine the size transition matrix.
4. An arbitrary $20 \%$ handling mortality rate on discarded males was used, which was obtained from the red king crab literature (Kruse et al. 2000; Siddeek 2002). An experimentally-based independent estimate of handling mortality is needed for Aleutian Islands golden king crab.
5. The Aleutian King Crab Research Foundation recently initiated crab survey programs in the Aleutian Islands. This program needs to be strengthened and continued for golden king crab research to address some of the data gaps and establish a fishery independent data source.
6. We have been using the length-weight relationship established based on late 1990s data for golden king crab. The Aleutian King Crab Research Foundation program can help us to update this relationship by collecting new length weight information.
7. We have recently included male maturity data in the model to determine a maturity curve for MMB estimation. The maturity data available to us were collected in 1984 and 1991. More data and recent data are needed.
8. Morphometric measurements provide morphometric maturity size. Ideally, an experimental study under natural environment condition is needed to collect male size at functional maturity data to determine functional maturity size.

## J. Acknowledgments

We thank Doug Pengilly, Leland Hulbert, Ethan Nichols, William Gaeuman, Robert Foy, Vicki Vanek, Bo Whiteside, and Andrew Nault for preparing/providing various fisheries and biological data and plots for this assessment; We appreciate the technical and editorial help at various time from Andre Punt, Martin Dorn, William Stockhausen, Steve Martel, Paul Starr, Sherri Dressel, Joel Webb, Katie Palof, Hamazaki Hamachan, Karla Bush, William Bechtol, CPT and SSC members, and industry personnel.

Note:
a. Includes deadloss.
b. Number of crab per pot lift.
c. Average weight of landed crab, including deadloss.
d. Managed with $6.5^{\prime \prime}$ carapace width (CW) minimum size limit.
e. Managed with $6.5^{\prime \prime} \mathrm{CW}$ minimum size limit west of $171^{\circ} \mathrm{W}$ longitude and $6.0^{\prime \prime}$ minimum size limit east of $171^{\circ} \mathrm{W}$ longitude.
f. Managed with 6.0" minimum size limit.

Catch and effort data include cost recovery fishery.

Table 2. Annual weight of total fishery mortality to Aleutian Islands golden king crab, 1981/82 2016/17, partitioned by source of mortality: retained catch, bycatch mortality during crab fisheries, and bycatch mortality during groundfish fisheries. For bycatch in the federal groundfish fisheries, historical data (1991-2008) are not available for areas east and west of 174 W , and are listed for federal groundfish reporting areas 541,542 , and 543 combined. The 2009- present data are available by separate EAG and WAG fisheries and are listed as such. A mortality rate of $20 \%$ was applied for crab fisheries bycatch, and a mortality rate of $50 \%$ for groundfish pot fisheries and $80 \%$ for the trawl fisheries were applied.

Table 2a. Time series of estimated total male catch (weight of crabs on the deck without applying any handling mortality) for the EAG and WAG golden king crab stocks (1990/91$2016 / 17$ ). The crab weights are for the size range $\geq 101 \mathrm{~mm}$ CL and Length-Weight formula was used to predict weight at the mid-point of each size bin. NA: no observer sampling to compute catch.

Table 16. Annual abundance estimates of model recruits (millions of crabs), legal male biomass ( t ) with coefficient of variations (CV), and mature male biomass ( t ) with CV for scenario 17_0b for golden king crab in the EAG. Legal male biomass was estimated on July 1 (start of fishing year) of fishing year y. Mature male biomass for fishing year y was estimated on February 15 of year $y+1$, after the year $y$ fishery total catch removal. Recruits estimates for 1961 to 2017 are restricted to 1985-2017. Equilibrium MMBeq and MMB35\% are also listed.

| Year | Recruits to the Model ( $\geq 101$ mm CL) | $\begin{gathered} \text { Mature Male } \\ \text { Biomass } \\ (\geq 111 \mathrm{~mm} \mathrm{CL}) \\ \hline \end{gathered}$ | CV | Legal Size Male Biomass ( $\geq 136$ mm CL) | CV |

Table 21. Negative log-likelihood values of the fits for scenarios (Sc) 17_0 (base), 17_0a (observer CPUE by VAST), 17_0b (observer and fishtick CPUE variable selection by CAIC), 17_0c (Year:Area interaction for observer and fishtick CPUE), 17_0d (three total selectivity and catchability for 1985-04, 2005-12, and 2013-16 time periods), 17_0e (Stage 2 effective sample sizes by McAllister and Ianelli method), and 17_0f (independent pot survey CPUE as an additional likelihood component) for golden king crab in the EAG. Differences in likelihood values are given for scenarios with the same number of data points (base) and free parameters. Likelihood components with zero entry in the entire rows are omitted. RetdcatchB= retained catch biomass.

Table 31. Annual abundance estimates of model recruits (millions of crabs), legal male biomass ( t ) with coefficient of variations (CV), and mature male biomass ( t ) with CV for scenario 17_0 for golden king crab in the WAG. Legal male biomass was estimated on July 1 (start of fishing year) of fishing year y. Mature male biomass for fishing year y was estimated on February 15 of year $y+1$, after the year y fishery total catch removal. Recruits estimates for 1961 to 2017 are restricted to 1985-2017. Equilibrium $\mathrm{MMB}_{\text {eq }}$ and $\mathrm{MMB}_{35 \%}$ are also listed.

| Year | Recruits to the <br> Model ( $\geq \mathbf{1 0 1}$ mm CL) | $\begin{gathered} \text { Mature Male } \\ \text { Biomass } \\ (\geq 111 \mathrm{~mm} \mathrm{CL}) \end{gathered}$ | CV | Legal Size Male Biomass ( $\geq 136$ mm CL) | CV |

Table 32. Annual abundance estimates of model recruits (millions of crabs), legal male biomass ( t ) with coefficient of variations (CV), and mature male biomass ( t ) CV for scenario 17_0a for golden king crab in the WAG. Legal male biomass was estimated on July 1 (start of fishing year) of fishing year y. Mature male biomass for fishing year y was estimated on February 15 of year $y+1$, after the year y fishery total catch removal. Recruits estimates for 1961 to 2017 are restricted to 1985-2017. Equilibrium $\mathrm{MMB}_{\mathrm{eq}}$ and $\mathrm{MMB}_{35 \%}$ are also listed.

| Year | Recruits to <br> the Model ( $\geq$ <br> 101 mm CL) | Mature Male <br> Biomass <br> $(\geq \mathbf{1 1 1 ~ m m ~ C L ) ~}$ | CV | Legal Size Male <br> Biomass ( $\geq \mathbf{1 3 6}$ <br> mm CL) | CV |

Figure 1. Total and components negative log-likelihoods vs. $M$ for scenario $\mathbf{0 b}$ model fit for EAG and WAG combined data. The $M$ estimate was obtained without any $M$ penalty. The $M$ estimate was $0.2254 \mathrm{yr}^{-1}\left( \pm 0.0199 \mathrm{yr}^{-1}\right)$. The negative log likelihood values were estimated for fixed proportions of estimated $M$ without using an $M$ penalty and they were zero adjusted. The $M$ profile indicates an $M$ value of $0.2142 \mathrm{yr}^{-1}$ at the minima of negative total likelihood for combined data as well as individual date sets. Hence an $M$ value of $0.21 \mathrm{yr}^{-1}$ was used in all scenarios.

Figure 2. Aleutian Islands, Area O, red and golden king crab management area (from Leon et al. 2017).

Figure 3. Adak (Area R) and Dutch Harbor (Area O) king crab registration area and districts, 1984/85-1995/96 seasons (Leon et al., 2017).

Figure 4. Percent of total 1981/82-1995/96 golden king crab retained catch weight (harvest) from one-degree longitude intervals in the Aleutian Islands, with dotted line denoting the border at $171^{\circ} \mathrm{W}$ longitude used during the 1984/85-1995/96 seasons to divide fishery management between the Dutch Harbor Area (east of $171^{\circ} \mathrm{W}$ longitude) and the Adak Area (west of $171^{\circ} \mathrm{W}$ longitude) and solid line denoting the border at $174^{\circ}$ W longitude used since the 1996/97 season to manage crab east and west of $174^{\circ} \mathrm{W}$ longitude (adapted from Figure 4-2 in Morrison et al. 1998).

Figure 5. Retained catch ( t ) of golden king crab within one-degree longitude intervals in the Aleutian Islands during the 2000/01 through 2016/17commercial fishery seasons; solid line denotes the border at $174^{\circ} \mathrm{W}$ longitude that has been used since the 1996/97 season to manage Aleutian Island golden king crab as separate stocks east and west of $174^{\circ} \mathrm{W}$ longitude and dashed line denotes the border at $171^{\circ} \mathrm{W}$ longitude used during the 1984/85-1995/96 seasons to divide fishery management between the Dutch Harbor Area (east of $171^{\circ} \mathrm{W}$ longitude) and the Adak Area (west of $171^{\circ} \mathrm{W}$ longitude).

Figure 6. Average golden king crab CPUE ( $\mathrm{kg} / \mathrm{nm} 2$ ) for tows, number of tows, and average depth of tows from one-degree longitude intervals during the 2002, 2004, 2006, 2010, and 2012 NMFS Aleutian Islands bottom trawl surveys; preliminary summary of data obtained on 1 April 2013 from http://www.afsc.noaa.gov/RACE/groundfish/survey_data/default.htm.

Figure 7. Historical commercial harvest (from fish tickets; metric tons) and catch-per-unit effort (CPUE, number of crabs per pot lift) of golden king crab in the EAG, 1985/86-2016/17 fisheries (note: 1985 refers to the 1985/86 fishing year).

Figure 8. Historical commercial harvest (from fish tickets; metric tons) and catch-per-unit effort (CPUE, number of crabs per pot lift) of golden king crab in the WAG, 1985/86-2016/17 fisheries (note: 1985 refers to the 1985/86 fishing year).

Figure 9. Catch distribution by statistical area.in 2016/17.

Figure 10. Standard deviation of recruit_dev plot for EAG and WAG. The mean recruit for years with standard deviation less than 0.7 sigma R was used to initialize model. We selected the 1987-2012 period for mean recruit estimation.

Figure 11. Predicted (line) vs. observed (bar) retained catch relative length frequency distributions under scenarios 17_0 (black line), 17_0a (orange line), 17_0b (red line), 17_0c (blue line), 17_0d (violet line), 17_0e (dark green line), and 17_0f (green line) for golden king crab in the EAG, 1985/86 to 2016/17. This color scheme is used in all other graphs.

Figure 12. Predicted (line) vs. observed (bar) total catch relative length frequency distributions under scenarios 17_0 to 17_0f for golden king crab in the EAG, 1990/91 to 2016/17.

Figure 13. Predicted (line) vs. observed (bar) groundfish (or trawl) discarded bycatch relative length frequency distributions under scenarios $17 \_0$ to $17 \_0 f$ for golden king crab in the EAG, 1989/90 to 2016/17. Note that this data set was not used in the model fitting.

Figure 14. Estimated total (black solid line) and retained selectivity (red dotted line) for pre- and post- rationalization periods under scenarios 17_0 to May 2017 Sc9 model fits to golden king crab data in the EAG.

Figure 15. Observed (open circles) vs. predicted (solid line) tag recaptures by size bin for years 1 to 6 recaptures under scenario 17_0 for EAG golden king crab.

Figure 16. Estimated number of male recruits (crab size $\geq 101 \mathrm{~mm} \mathrm{CL}$ ) to the assessment model under scenarios (Sc) 17_0 to May 2017 Sc9 for EAG golden king crab data, 1961-2017. Top left: scenarios 17_0 and 17_0a; top right: scenarios 17_0, 17_0b, and 17_0c; bottom left: scenarios 17_0, 17_0d, and 17_0e; and bottom right: scenarios 17_0, 17_0f, and May 2017 Sc9. This grouping scheme was used in a number of subsequent figures. The number of recruits are centralized using ( R -mean R )/mean R for comparing different scenarios' results.

Figure 17. Recruit size distribution to the assessment model under scenarios (Sc) 17_0 to May 2017 Sc9 for EAG golden king crab.

Figure 19. Observed (open circle) vs. predicted (solid line) retained catch (top left in each scenario set), total catch (top right in each scenario set), and groundfish bycatch (bottom left in each scenario set) of golden king crab for scenarios 17_0 to May 2017 Sc9, in EAG, 1981/822016/17.

Figure 20. Observed (open circle) vs. predicted (solid line) retained catch of golden king crab for scenarios 17_0 to May 2017 Sc9 fits in the EAG, 1981/82-1984/85. Note: Input retained catches to the model during pre-1985 fishery period were in number of crabs.

EAG 17_0 Retained Catch Size Composition Standardized Residuals

Figure 21. Bubble plot of standardized residuals of retained catch length composition for scenario 17_0 fit for EAG golden king crab, 1985/86-2016/17. Green circles are the positive and pink circles are the negative standardized residuals. The area of the circle is the relative magnitude of the residual.

EAG 17_0 Total Catch Size Composition Standardized Residuals

Figure 22. Bubble plot of standardized residuals of total catch length composition for scenario $17 \_0$ fit for EAG golden king crab, 1990/91-2016/17. Green circles are the positive and pink circles are the negative standardized residuals. The area of the circle is the relative magnitude of the residual.

Figure 23. Bubble plot of standardized residuals of retained catch length composition for scenario 17_0d fit for EAG golden king crab, 1985/86-2015/16. Blue circles are the positive and
pink circles are the negative standardized residuals. The area of the circle is the relative magnitude of the residual.

Figure 24. Bubble plot of standardized residuals of total catch length composition for scenario 9 fit for EAG golden king crab, 1990/91-2015/16. Blue circles are the positive and pink circles are the negative standardized residuals. The area of the circle is the relative magnitude of the residual.

Figure 25. Retrospective fits of MMB by the model following removal of terminal year data under scenarios 17_0 (top) and 17_0d (bottom) for golden king crab in the EAG, 1960/612016/17.

Mohn rho ( $\rho$ ) formula (modified by Deroba, 2014) is as follows:

$$
\text { Mohn } \rho=\frac{\sum_{n=1}^{x} \frac{\left[\widehat{M M B}_{y=T-n, T-n}-\widehat{M M B}_{y=T-n, T}\right]}{\widehat{M M B}_{y=T-n, T}}}{x}
$$

where, $\widehat{M M B}_{y=T-n, T-n}$ is the MMB estimated for year T-n (left subscript) using data up to T-n years (right subscript), T is the terminal year of the entire data, x is the total number of peels, most recent year's data is "peeled off" recursively n times, where $\mathrm{n}=1,2,3$. ...x.
We used four peels ( $x=4$ ) and our $T=2016$.

Figure 26. Comparison of input CPUE indices (open circles with $+/-2$ SE) with predicted CPUE indices (colored solid lines) under scenarios 17_0 to May 2017 Sc9 for EAG golden king crab data, 1985/86-2016/17. Model estimated additional standard error was added to each input standard error.

Figure 27. Trends in pot fishery full selection total fishing mortality of golden king crab for scenarios 17_0 to May 2017 Sc9 model fits in the EAG, 1981/82-2016/17.

Figure 46. Trends in golden king crab mature male biomass for scenarios $17 \_0$ to May 2017 Sc9 model fits in the WAG, 1960/61-2016/17. Scenario 17_0 estimates have two standard errors confidence limits.

Figure 47. Relationships between full fishing mortalities for the directed pot fishery and mature male biomass on Feb. 15 during 1985/86-2016/17 under scenarios 17_0 and 17_0d for EAG and WAG. Average recruitment from 1987 to 2012 was used to estimate $M_{3}{ }_{35 \%}$. Pot and groundfish handling mortality rates were assumed to be 0.2 and 0.65 , respectively.

## Appendix A: Integrated model

Aleutian Islands Golden King Crab (Lithodes aequispinus) Stock Assessment Model Development- east of $174^{\circ} \mathrm{W}$ (EAG) and west of $174^{\circ} \mathrm{W}$ (WAG) Aleutian Island stocks

## Basic population dynamics

The annual [male] abundances by size are modeled using the equation:
$N_{t+1, j}=\sum_{i=1}^{j}\left[N_{t, i} e^{-M}-\left(\hat{C}_{t, i}+\widehat{D}_{t, i}+\widehat{\operatorname{Tr}}_{t, i}\right) e^{\left(y_{t}-1\right) M}\right] X_{i, j}+R_{t+1, j}$
where $N_{t, i}$ is the number of [male] crab in length class i on 1 July (start of fishing year) of year t; $\hat{C}_{t, i}, \hat{D}_{t, i}$, and $\hat{T} r_{t, i}$ are respectively the predicted fishery retained, pot fishery discard dead, and groundfish fishery discard dead catches in length class $i$ during year $t, \widehat{D}_{t, i}$ is estimated from the intermediate total ( $\hat{T}_{t, i \text { temp }}$ ) catch and the retained ( $\hat{C}_{t, i}$ ) catch by Equation A.2c. ${ }^{X_{i, j}}$ is the probability of length-class $i$ growing into length-class $j$ during the year; $y_{t}$ is elapsed time period from 1 July to the mid -point of fishing period in year $t ; M$ is instantaneous rate of natural mortality; and $R_{t+1, j}$ recruitment to length class $j$ in year $t+1$.

The catches are predicted using the equations
$\widehat{T}_{t, j, \text { temp }}=\frac{F_{t} s_{t, j}^{T}}{Z_{t, j}} N_{t, j} e^{-y_{t} M}\left(1-e^{-Z_{t, j}}\right)$
$\hat{C}_{t, j}=\frac{F_{t} S_{t, j}^{T} s_{t, j}^{r}}{z_{t, j}} N_{t, j} e^{-y_{t} M}\left(1-e^{-Z_{t, j}}\right)$
$\widehat{D}_{t, j}=0.2\left(\widehat{T}_{t, j, t e m p}-\hat{C}_{t, j}\right)$
$\widehat{T r}_{t, j}=0.65 \frac{F_{t}^{T r} s_{j}^{T r}}{z_{t, j}} N_{t, j} e^{-y_{t} M}\left(1-e^{-Z_{t, j}}\right)$
$\widehat{T}_{t, j}=\hat{C}_{t, j}+\widehat{D}_{t, j}$
where $Z_{t, j}$ is total fishery-related mortality on animals in length-class $j$ during year $t$ :

$$
\begin{equation*}
Z_{t, j}=F_{t} s_{t, j}^{T} s_{t, j}^{r}+0.2 F_{t} s_{t, j}^{T}\left(1-s_{t, j}^{r}\right)+0.65 F_{t}^{T r} s_{j}^{T r} \tag{A.3}
\end{equation*}
$$

$F_{t}$ is the full selection fishing mortality in the pot fishery, $F_{t}^{T r}$ is the full selection fishing mortality in the trawl fishery, $s_{t, j}^{T}$ is the total selectivity for animals in length-class $j$ by the pot fishery during year $t, s_{j}^{T r}$ is the selectivity for animals in length-class $j$ by the trawl fishery, $s_{t, j}^{r}$ is the probability of retention for animals in length-class $j$ by the pot fishery during year $t$. Pot
bycatch mortality of 0.2 and groundfish bycatch mortality of 0.65 (average of trawl (0.8) and fish pot ( 0.5 ) mortality) were assumed.

## Initial abundance

The initial conditions are computed as the equilibrium initial condition using the following relations:

The equilibrium stock abundance is
$N=X . S . N+R$
The equilibrium abundance in $1960, N_{1960}$, is
$\underline{N}_{1960}=(I-X S)^{-1} \underline{R}$
where $X$ is the growth matrix, $S$ is a matrix with diagonal elements given by $e^{-M}, I$ is the identity matrix, and $\underline{R}$ is the product of average recruitment and relative proportion of total recruitment to each size-class.

We used the mean number of recruits from 1987 to 2012 in equation (A.5) to obtain the equilibrium solution under only natural mortality in year 1960, and then projected the equilibrium abundance under natural mortality with recruitment estimated for each year after 1960 up to 1985 with removal of retained catches during 1981/82 to 1984/85.

## Growth Matrix

The growth matrix $X$ is modeled as follows:
$X_{i, j}= \begin{cases}0 & \text { if } j<i \\ P_{i, j}+\left(1-m_{i}\right) & \text { if } j=i \\ P_{i, j} & \text { if } j>i\end{cases}$
where:

$$
P_{i, j}=m_{i}\left\{\begin{array}{cr}
\int_{-\infty}^{j_{2}-L_{i}} N\left(x \mid \mu_{i}, \sigma^{2}\right) d x & \text { if } j=i \\
\int_{j_{1}-L_{i}}^{j_{2}-L_{i}} N\left(x \mid \mu_{i}, \sigma^{2}\right) d x & \text { if } i<j<n  \tag{A.7}\\
\int_{j_{1}-L_{i}}^{\infty} N\left(x \mid \mu_{i}, \sigma^{2}\right) d x & \text { if } i=n
\end{array}, \begin{array}{c}
N\left(x \mid \mu_{i}, \sigma^{2}\right)=\frac{1}{\sqrt{2 \pi \sigma^{2}}} e^{-\left(\frac{x-\mu_{i}}{\sqrt{2} \sigma}\right)^{2}}, \text { and }
\end{array}\right.
$$

$\mu_{i}$ is the mean growth increment for crab in size-class $i$ :
$\mu_{i}=\omega_{1}+\omega_{2} * \bar{L}_{i}$.
$\omega_{1} \quad, \omega_{2}, \quad$ and $\sigma$ are estimable parameters, and $j_{1}$ and $j_{2}$ are the lower and upper limits of the receiving length-class $j$ (in mm CL), and $\bar{L}_{i}$ is the mid-point of the contributing length interval $i$. The quantity $m_{i}$ is the molt probability for size-class $i$ :
$m_{i}=\frac{1}{1+e^{c\left(\tau_{i}-d\right)}}$
where $\tau_{i}$ is the mid-length of the $i$-th length-class, $c$ and $d$ are parameters.

## Selectivity and retention

Selectivity and retention are both assumed to be logistic functions of length. Selectivity depends on the fishing period for the pot fishery:
$S_{i}=\frac{1}{1+e^{\left[-\ln \left(199 \frac{\tau_{i}-\theta_{50}}{\left.\theta_{95}-\theta_{50}\right]}\right.\right.}}$
where $\theta_{95}$ and $\theta_{50}$ are the parameters of the selectivity/ retention pattern (Mark Maunder, unpublished generic crab model). In the program, we re-parameterized the denominator ( $\theta_{95}$ $\left.\theta_{50}\right)$ to $\log (\operatorname{delta} \theta)$ so that the difference is always positive and transformed $\theta_{50}$ to $\log \left(\theta_{50}\right)$ to keep the estimate always positive.

Recruitment
Recruitment to length-class i during year $t$ is modeled as $R_{t, i}=\bar{R} e^{\epsilon_{i}} \Omega_{i}$ where $\Omega_{i}$ is a normalized gamma function

$$
\begin{equation*}
\operatorname{gamma}\left(x \mid \alpha_{r}, \beta_{r}\right)=\frac{x^{\alpha_{r}-1} e^{\frac{x}{\beta_{r}}}}{\beta_{r}{ }^{\alpha_{r}} \Gamma_{\left(\alpha_{r}\right)}} \tag{A.10}
\end{equation*}
$$

with $\alpha_{r}$ and $\beta_{r}$ (restricted to the first five length classes).

## Parameter estimation

Table A1 lists the parameters of the model indicating which are estimated and which are prespecified. The objective function includes contributions related to the fit of the model to the available data and penalties (priors on various parameters).

Tables A2 lists parameter values (with the corresponding coefficient of variations in parentheses) used to weight the components of the objective functions for EAG and WAG.

## Likelihood components

## Catches

The contribution of the catch data (retained, total, and groundfish discarded) to the objective function is given by:

$$
\begin{align*}
& L L_{r}^{\text {catch }}=\lambda_{r} \sum_{t}\left\{\ln \left(\sum_{j} \hat{C}_{t, j} w_{j}+c\right)-\ln \left(\sum_{j} C_{t, j} w_{j}+c\right)\right\}^{2}  \tag{A.11a}\\
& L L_{T}^{\text {catch }}=\lambda_{T} \sum_{t}\left\{\ln \left(\sum_{j} \widehat{T}_{t, j} w_{j}+c\right)-\ln \left(\sum_{j} T_{t, j} w_{j}+c\right)\right\}^{2}  \tag{A.11b}\\
& L L_{G D}^{\text {catch }}=\lambda_{G D} \sum_{t}\left\{\ln \left(\sum_{j} \widehat{T r}_{t, j} w_{j}+c\right)-\ln \left(\sum_{j} T r_{t, j} w_{j}+c\right)\right\}^{2} \tag{A.11c}
\end{align*}
$$

where $\lambda_{r}, \lambda_{T}$, and $\lambda_{G D}$ are weights assigned to likelihood components for the retained, pot total, and groundfish discard catches; ${ }_{j}$ is the average mass of a crab is length-class $j ;{ }^{C_{t, j}}, T_{t, j}$, and $T r_{t, j}$ are, respectively, the observed numbers of crab in size class $j$ for retained, pot total, and groundfish fishery discarded crab during year $t$, and $c$ is a small constant value. We assumed $c=$ 0.001 .

An additional retained catch likelihood (using Equation A.11a without w) for the retained catch in number of crabs during 1981/82 to 1984/85 was also considered in all scenarios.

## Catch-rate indices

The catch-rate indices are assumed to be lognormally distributed about the model prediction. Account is taken of variation in addition to that related to sampling variation:
$\left.\left.L L_{r}^{\text {CPUE }}=\lambda_{r, C P U E}\left\{0.5 \sum_{t} \ln \left[2 \pi\left(\sigma_{r, t}^{2}+\sigma_{e}^{2}\right)\right]+\sum_{t} \frac{\left(\ln \left(C P U E_{t}^{r}+c\right)-\ln (C \widehat{P U E} r\right.}{t}+c\right)\right)^{2}\right\}$
where ${ }^{C P U E} E_{t}^{r}$ is the standardized retain catch-rate index for year $t,{ }^{\sigma_{r, t}}$ is standard error of the logarithm of $C P U E_{t}^{r}$, and $C \widehat{P U E}_{t}^{r}$ is the model-estimate of $C P U E_{t}^{r}$ :

$$
\begin{equation*}
\widehat{C P U E}_{t}^{r}=q_{k} \sum_{j} S_{j}^{T} S_{j}^{r}\left(N_{t, j}-0.5\left[\widehat{C_{t, j}}+\widehat{D_{t, j}}+\widehat{T r_{t, j}}\right]\right) e^{-y_{t} M} \tag{A.13}
\end{equation*}
$$

in which $q_{k}$ is the catchability coefficient during the $k$-th time period (e.g., pre- and postrationalization time periods), $\sigma_{e}$ is the extent of over-dispersion, $c$ is a small constant to prevent zero values (we assumed $c=0.001$ ), and $\lambda_{r, C P U E}$ is the weight assigned to the catch-rate data. We used the same likelihood formula (A.12) for fish ticket retained catch rate indices.

Following Burnham et al. (1987), we computed the $\ln$ (CPUE) variance by:

$$
\begin{equation*}
\sigma_{\mathrm{r}, \mathrm{t}}^{2}=\ln \left(1+C V_{\mathrm{r}, \mathrm{t}}^{2}\right) \tag{A.14}
\end{equation*}
$$

## Length-composition data

The length-composition data are included in the likelihood function using the robust normal for proportions likelihood, i.e., generically:
$L L_{r}^{L F}=0.5 \sum_{t} \sum_{j} \ln \left(2 \pi \sigma_{t, j}^{2}\right)-\sum_{t} \sum_{j} \ln \left[\exp \left(-\frac{\left(P_{t, j}-\hat{P}_{, j}\right)^{2}}{2 \sigma_{t, j}^{2}}\right)+0.01\right]$
where $P_{t, j}$ is the observed proportion of crabs in length-class j in the catch during year $\mathrm{t},{ }^{2} \hat{P}_{t, j}$ is the model-estimate corresponding to ${ }^{P_{t, j}}$, i.e.:
$\widehat{\mathrm{L}}_{\mathrm{t}, \mathrm{j}}^{\mathrm{r}}=\frac{\widehat{\mathrm{C}}_{\mathrm{t}, \mathrm{j}}}{\sum_{\mathrm{j}}^{\mathrm{n}} \mathrm{C}_{\mathrm{t}, \mathrm{j}}}$
$\hat{\mathrm{L}}_{\mathrm{t}, \mathrm{j}}^{\mathrm{T}}=\frac{\widehat{\mathrm{T}}_{\mathrm{t}, \mathrm{j}}}{\sum_{\mathrm{j}}^{\mathrm{n}} \mathrm{T}_{\mathrm{t}, \mathrm{j}}}$
$\hat{\mathrm{L}}_{\mathrm{t}, \mathrm{j}}^{\mathrm{GF}}=\frac{\widehat{\mathrm{Tr}}_{\mathrm{t}, \mathrm{j}}}{\sum_{\mathrm{j}}^{\mathrm{n}} \mathrm{Tr}_{\mathrm{t}, \mathrm{j}}}$
$\sigma_{t, j}^{2}$ is the variance of $P_{t, j}$ :
$\sigma_{t, j}^{2}=\left[\left(1-P_{t, j}\right) P_{t, j}+\frac{0.1}{n}\right] / S_{t}$
and $S_{t}$ is the effective sample size for year $t$ and $n$ is the number of size classes.

Note: The likelihood calculation for retained length composition starts from length-class 6 (mid length 128 mm CL ) because the length-classes 1 to 5 mostly contain zero data.

## Tagging data

Let $V_{j, t, y}$ be the number of tagged male crab that were released during year $t$ that were in sizeclass $j$ when they were released and were recaptured after $y$ years, and $\underline{\rho}_{j, t, y}$ be the vector of recaptures by size-class from the males that were released in year $t$ that were in size-class $j$ when they were released and were recaptured after $y$ years. The log-likelihood corresponding to the multinomial distribution for the tagging data is then:
$\ln L=\lambda_{y, t a g} \sum_{j} \sum_{t} \sum_{y} \sum_{i} \rho_{j, t, y, i} \ln \hat{\rho}_{j, t, y, i}$
where $\lambda_{y, t a g}$ is the weight assigned to the tagging data for recapture year $y, \hat{\rho}_{j, t, y, i}$ is the proportion in size-class $i$ of the recaptures of males that were released during year $t$ that were in size-class $j$ when they were released and were recaptured after $y$ years:

$$
\begin{equation*}
\underline{\hat{\rho}}_{j, t, y} \propto \underline{s}^{T}[\mathbf{X}]^{y} \underline{Z}^{(j)} \tag{A19}
\end{equation*}
$$

where $Z^{(j)}$ is a vector with $V_{j, t, y}$ at element $j$ and 0 otherwise, and $S^{T}$ is the vector of total selectivities for tagged male crab by the pot fishery. This log-likelihood function is predicated on the assumption that all recaptures are in the pot fishery and the reporting rate is independent of the size of crab.

## Penalties

Penalties are imposed on the deviations of annual pot fishing mortality about mean pot fishing mortality, annual trawl fishing mortality about mean trawl fishing mortality, recruitment about mean recruitment, and the posfunction (fpen):

$$
\begin{align*}
& P_{1}=\lambda_{F} \sum_{t}\left(\ln F_{t}-\ln \bar{F}\right)^{2}  \tag{A.20}\\
& P_{2}=\lambda_{F^{T r}} \sum_{t}\left(\ln F_{t}^{T r}-\ln \bar{F}^{T r}\right)^{2} \tag{A.21}
\end{align*}
$$

$$
\begin{align*}
& P_{3}=\lambda_{R} \sum_{t}\left(\ln \varepsilon_{t}\right)^{2}  \tag{A.22}\\
& P_{5}=\lambda_{\text {posfn }} * \text { fpen } \tag{A.23}
\end{align*}
$$

## Standardized Residual of Length Composition

$$
\begin{equation*}
\text { Std. } \operatorname{Res}_{\mathrm{t}, \mathrm{j}}=\frac{\mathrm{P}_{\mathrm{t}, \mathrm{j}}-\stackrel{P}{\mathrm{t}, \mathrm{j}}}{\sqrt{2 \sigma_{\mathrm{t}, \mathrm{j}}^{2}}} \tag{A.24}
\end{equation*}
$$

## Output Quantities

## Harvest rate

Total pot fishery harvest rate:

$$
\begin{equation*}
E_{t}=\frac{\sum_{j=1}^{n}\left(\hat{\mathrm{C}}_{\mathrm{j}, t}+\stackrel{\rightharpoonup}{\mathrm{j}}, \mathrm{t}\right)}{\sum_{j=1}^{\mathrm{N}} \mathrm{~N}_{\mathrm{j}, \mathrm{t}}} \tag{A.25}
\end{equation*}
$$

Exploited legal male biomass at the start of year $t$ :
$L M B_{t}=\sum_{j=\text { legal size }}^{n} s_{j}^{T} s_{j}^{r} N_{j, t} w_{j}$
where $w_{j}$ is the weight of an animal in length-class $j$.
Mature male biomass on 15 February spawning time (NPFMC 2007) in the following year:
MMB $_{\mathrm{t}}=\sum_{\mathrm{j}=\text { mature size }}^{\mathrm{n}}\left\{\mathrm{N}_{\mathrm{j}, \mathrm{t}} \mathrm{e}^{-\mathrm{y}^{\prime} \mathrm{M}}-\left(\widehat{\mathrm{C}}_{\mathrm{j}, \mathrm{t}}+\widehat{\mathrm{D}}_{\mathrm{j}, \mathrm{t}}+\widehat{\operatorname{Tr}}_{\mathrm{j}, \mathrm{t}}\right) \mathrm{e}^{\left(\mathrm{y}_{\mathrm{t}}-\mathrm{y}\right) \mathrm{M}}\right\} \mathrm{w}_{\mathrm{j}}$
where $y^{\prime}$ is the elapsed time from 1 July to 15 February in the following year.
For estimating the next year limit harvest levels from current year stock abundances, a $F_{\text {OFL }}$ value is needed. Current crab management plan specifies five different Tier formulas for different stocks depending on the strength of information available for a stock, for computing $F_{O F L}$ (NPFMC 2007). For the golden king crab, the following Tier 3 formula is applied to compute $F_{O F L}$ :

$$
\begin{align*}
& \text { If, } \\
& M M B_{\text {current }}>M M B_{35 \%}, F_{O F L}=F_{35 \%} \\
& \text { If, } \\
& M M B_{\text {current }} \leq M M B_{35 \%} \text { and } M M B_{\text {current }}>0.25 M M B_{35 \%}, \\
& F_{O F L}=F_{35 \%} \frac{\left(\frac{M M B_{\text {current }}}{M M B_{35 \%}}-\alpha\right)}{(1-\alpha)} \tag{A.28}
\end{align*}
$$

If,
$M M B_{\text {current }} \leq 0.25 M M B_{35 \%}$,
$F_{O F L}=0$.
where $\alpha$ is a parameter, $\mathrm{MMB}_{\text {current }}$ is the mature male biomass in the current year and $M M B_{35 \%}$ is the proxy $M M B_{M S Y}$ for Tier 3 stocks. We assumed $\alpha=0.1$.
Because projected $\mathrm{MMB}_{\mathrm{t}}$ (i.e., $\mathrm{MMB}_{\text {current }}$ ) depends on the intervening retained and discard catch (i.e., $\mathrm{MMB}_{\mathrm{t}}$ is estimated after the fishery), an iterative procedure is applied using Equations A. 27 and A. 28 with retained and discard catch predicted from Equations A.2b-d. The next year limit harvest catch is estimated using Equations A.2b-d with the estimated $F_{O F L}$ value.

## Appendix B: Catch and CPUE data

The commercial catch and length frequency distribution were estimated from ADF\&G landing records and dockside sampling (Bowers et al. 2008, 2011). The annual retained catch, total catch, and groundfish (or trawl) discarded mortality are provided in Tables 1, 2, and $2 b$ for EAG and WAG. The weighted length frequency data were used to distribute the catch into $5-\mathrm{mm}$ size intervals. The length frequency data for a year were weighted by each sampled vessel's catch as follows. The $i$-th length-class frequency was estimated as:

$$
\begin{equation*}
\sum_{j=1}^{k} C_{j} \frac{L F_{j, i}}{\sum_{i=1}^{n} L F_{j, i}} \tag{B.1}
\end{equation*}
$$

where $k=$ number of sampled vessels in a year, $L F_{j, i}=$ number of crabs in the $i$-th lengthclass in the sample from $j$-th vessel, $\mathrm{n}=$ number of size classes, $C_{j}=$ number of crabs caught by $j$-th vessel. Then the relative frequency for the year was calculated and applied to the annual retained catch (in number of crabs) to obtain retained catch by length-class.

The annual total catch (in number of crabs) was estimated by the observer nominal (unstandardized) total CPUE considering all vessels multiplied by the total fishing effort (number of pot lifts). The weighted length frequency of the observer samples across the fleet was estimated using Equation B.1. Observer measurement of crab ranged from 20 to 220 mm CL. To restrict the total number of crabs to the model assumed size range (101-185+ mm CL ), the proportion of observer total relative length frequency corresponding to this size range was multiplied by the total catch (number of crabs). This total number of crabs was distributed into length-classes using the weighted relative length frequency. Thus, crab sizes $<101 \mathrm{~mm}$ CL were excluded from the model. In addition, all crab > 185 mm CL were pooled into a plus length class. Note that the total crab catch by size that went into the model did not consider retained and discard components separately. However, once the model estimated the annual total catch, then retained catch was deducted from this total and multiplied by handling mortality [we used a $20 \%$ handling mortality (Siddeek et al. 2005) to obtain the directed fishery discarded (dead) catch].

Observer data have been collected since 1988 (Moore et al. 2000; Barnard et al. 2001; Barnard and Burt 2004; Gaeuman 2011), but data were not comprehensive in the initial years, so a shorter time series of data for the period 1990/91-2016/17 was selected for this analysis. During 1990/91-1994/95, observers were only deployed on catcher-processor vessels. During 1995/96-2004/05, observers were deployed on all fishing vessels during fishing activity. Observers have been deployed on all fishing vessels since 2005/06, but catcher-only vessels are only required to carry observers for a minimum of $50 \%$ of their fishing activity during a season; catcher-processor vessels are still required to carry observers during all fishing activity. Onboard observers sample seven pots per day (it can be different number of pots per string) and count and measure all crabs caught and categorize catch as females, sublegal males, retained legal males, and non-retained legal males in a sampled pot. Prior to the 2009/10 season, depending on season, area, and type of fishing vessel, observers were also instructed to sample additional pots in which all crab were only counted and categorized as females, sublegal males, retained legal males, and non-retained legal males, but were not measured. Annual mean nominal CPUEs of retained and total crabs were estimated considering all sampled pots within each season (Table 3). The observer CPUE
data collection improved over the years and the data since 1995/96 are more reliable. Thus, for model fitting, the observer CPUE time series was restricted to 1995/96-2016/17. The 1990/91-2016/17 observer database consists of 112,510 records and that of 1995/96-2016/17 contains 108,231 records, For CPUE standardization, these data were further reduced by $5 \%$ cutoff of Soak time and $1 \%$ cutoff of Depth on both ends of the variable range to remove unreliable data or data from dysfunctional pot operations, and restricting to vessels which have made five trips per year for at least three years during 1985/86-2016/17.

Length-specific CPUE data collected by observers provides information on a wider size range of the stock than did the commercial catch length frequency data obtained from mostly legal-sized landed males.

There were significant changes in fishing practice due to changes in management regulations (e.g., since 1996/97 constant TAC and since 2005/06 crab rationalization), pot configuration (escape web on the pot door increased to 9 " since 1999), and improved observer recording in Aleutian Islands golden king crab fisheries since 1998. These changes prompted us to consider two separate observer CPUE time series, 1995/96-2004/05 and 2005/06-2016/17, to estimate CPUE indices for model input.

To include a long time series of CPUE indices for stock abundance contrast, we also considered the 1985/86-1998/99 legal size standardized CPUE as a separate likelihood component in all scenarios. Because of the lack of soak time data previous to 1990, we estimated the CPUE index considering a limited set of explanatory variables (e.g., vessel, captain, area, month) and fitting the lognormal GLM to fish ticket data (Tables 4 and 26).

When using CPUE indices in the model fit, we compared the predicted with the observed legal male CPUE in the observer CPUE likelihoods because legal male (retained plus nonretained) data are more reliable than total in the observer samples.

Most scenarios used CPUE indices estimated by the GLM method. One scenario (17_0a) used the deltaGLMM spatio-temporal method (VAST, Thorson et al., 2015) to estimate observer CPUE indices. We describe both below:

## a. Observer CPUE index by GLM:

The CPUE standardization followed the GLM fitting procedure (Maunder and Punt 2004; Starr 2012; Siddeek et al. 2016b). We considered the negative binomial GLM on positive and zero catches to select the explanatory variables. The response variable CPUE is the observer sample catch record for a pot haul. The negative binomial model uses the log link function for the GLM fit. Therefore, we assumed the null model to be

$$
\begin{equation*}
\ln \left(\text { CPUE }_{i}\right)=\text { Year }_{y_{i}} \tag{B.2}
\end{equation*}
$$

where Year is a factorial variable.
The maximum set of model terms offered to the stepwise selection procedure was:

$$
\begin{align*}
& \ln \left(\text { CPUE }_{I}\right)=\text { Year }_{y_{i}}+\text { ns }\left(\text { Soak }_{\text {si }}, \text { df }\right)+\text { Month }_{m_{i}}+\text { Vessel }_{\text {vi }}+\text { Captain }_{\text {ci }}+\text { Area }_{\text {ai }}+ \\
& \operatorname{Gear}_{\mathrm{gi}}+\mathrm{ns}\left(\text { Depth }_{\text {di }}, \text { df }\right)+\text { ns }\left(\text { VesSoak }_{\text {vsi }}, \text { df }\right), \tag{B.3}
\end{align*}
$$

where Soak is in unit of days and is numeric; Month, Area code, Vessel code, Captain code, and Gear code are factorial variables; Depth in fathom is a numeric variable; VesSoak is a numeric variable computed as annual number of vessels times annual mean soak days (to account for other vessels' effect on CPUE); ns=cubic spline, and $\mathrm{df}=$ degree of freedom.

We used a log link function and a dispersion parameter $(\theta)$ in the GLM fitting process. We used the $\mathrm{R}^{2}$ criterion for predictor variable selection (Siddeek et al. 2016b).

The $\mathrm{R}^{2}$ formula for explanatory variable selection is as follows:
$R^{2}=\frac{(n u l l \text { model deviance-added parameter model deviance) }}{\text { null model deviance }}$
An arbitrary $\mathrm{R}^{2}$ minimum increment of 0.01 was set to select the model terms.
First we determined the dispersion parameter $(\theta)$ by a grid search method (Fox and Weisberg, 2011). The best $\theta$ value was obtained at the minimum AIC:

Table B.1. Dispersion parameter search.

|  | Time Period | $\boldsymbol{\theta}$ | AIC |
| :--- | :--- | :--- | :--- |
| EAG | $1995 / 96-2004 / 05$ | 1.37 | 223,933 |
|  | $2005 / 06-2016 / 17$ | 2.30 | 59,284 |
|  |  |  |  |
| WAG | $1995 / 96-2004 / 05$ | 1.00 | 196,290 |
|  | $2005 / 06-2016 / 17$ | 1.17 | 94,190 |

Then we used the optimized dispersion parameter value in the GLM model for individual predictor variable fit to determine appropriate df value based on the minimum AIC:

Table B.2. Predictor variable degree of freedom search.

|  | Time Period | Predictor <br> Variable | Df | AIC |
| :---: | :---: | :---: | :---: | :---: |
| EAG | 1995/96-2004/05 | Soak | 4 | 235,222 |
|  |  | Depth | 2 | 237,098 |
|  |  | VesSoak | 9 | 232,152 |
|  | 2005/06-2016/17 | Soak | 11 | 59,988 |
|  |  | Depth | 6 | 60,215 |
|  |  | VesSoak | 4 | 59,982 |
| WAG | 1995/96-2004/05 | Soak | 10 | 201,755 |
|  |  | Depth | 9 | 205,398 |
|  |  | VesSoak | 7 | 204,841 |
|  | 2005/06-2016/17 | Soak | 5 | 95,181 |
|  |  | Depth | 2 | 95,202 |
|  |  | VesSoak | 4 | 94,954 |

We also used the "stepAIC" package (R Core Team, 2018) for forward selection of predictor variables for CPUE standardization for scenarios EAG17_0b and WAG17_0b, respectively. Instead of using the traditional AIC (-2log_likelihood+2p) we used CAIC \{$2 \log _{\_}$likelihood $\left.+[\ln (\mathrm{n})+1] \mathrm{p}\right\}$ for variable selection, where $\mathrm{n}=$ number of observations and $\mathrm{p}=$ number of parameters to be estimated.

The final main effect models for EAG were:
Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Gear + Captain + Area + ns(Soak, 4)
for the 1995/96-2004/05 period $\left[\theta=1.37, \mathrm{R}^{2}=0.2473\right.$, $\left.\mathrm{AIC}=223,933\right]$
Under CAIC selection criteria:
$\ln ($ CPUE $)=$ Year + Gear + Captain + ns $($ Soak, 4$)+$ Month + Area
for the 1995/96-2004/05 period $\left[\theta=1.37, \mathrm{R}^{2}=0.2563\right.$, $\left.\mathrm{AIC}=224,707\right]$
Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Captain + Gear + ns $($ Soak, 11)
for the 2005/06-2016/17 period $\left(\theta=2.30, \mathrm{R}^{2}=0.1177\right.$, $\left.\mathrm{AIC}=59,284\right)$.
Under CAIC selection criteria:
$\ln ($ CPUE $)=$ Year + Vessel + Gear + ns(Soak, 11)
for the 2005/06-2016/17 period $\left(\theta=2.30, R^{2}=0.1143, \mathrm{AIC}=59,610\right)$.
The final models for WAG were:

Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Captain + Gear + ns (Soak, 10) + Area
for the 1995/96-2004/05 period $\left[\theta=1.00, \mathrm{R}^{2}=0.2031\right.$, $\left.\mathrm{AIC}=196,290\right]$
Under CAIC selection criteria:

$$
\begin{equation*}
\ln (\text { CPUE })=\text { Year }+ \text { Captain }+ \text { Gear }+ \text { ns }(\text { Soak, } 10)+\text { Month }+ \tag{B.10}
\end{equation*}
$$

Vessel + ns(Depth, 9)
for the 1995/96-2004/05 period $\left[\theta=1.00, R^{2}=0.1948, \mathrm{AIC}=197,640\right]$
Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Area + Gear $+\mathrm{ns}($ Soak, 5$)$
for the 2005/06-2016/17 period
$\left[\theta=1.17, \mathrm{R}^{2}=0.0831\right.$, AIC $=94,190$ with $\mathrm{ns}($ Soak, 5$)$ forced in$]$
Under CAIC selection criteria:
$\ln ($ CPUE $)=$ Year + Gear + Vessel + ns $($ Depth, 2$)+$ Month
+ns(Soak, 5)
for the 2005/06-2016/17 period
$\left[\theta=1.17, R^{2}=0.0684\right.$, AIC $=94,699$ with ns(Soak, 5$)$ forced in]

The final model after adding the Year:Area interaction term in the scope of variables for EAG were:

$$
\begin{equation*}
\ln (\text { CPUE })=\text { Year }+ \text { Gear }+ \text { Captain }+ \text { Area }+ \text { Year: Area }+ \text { ns }(\text { Soak }, 4) \tag{B.13}
\end{equation*}
$$

for the 1995/96-2004/05 period
$\left[\theta=1.37, \mathrm{R}^{2}=0.2684, \mathrm{AIC}=223,164\right.$ with $\mathrm{ns}($ Soak, 4$)$ forced in ]
Note: A number of indeterminate parameter values for interaction factors were observed. However, as per January 2018 CPT request, we used the resulting CPUE indices in scenario EAG17_0c.
$\ln ($ CPUE $)=$ Year + Captain + Gear + ns $($ Soak, 11)
for the 2005/06-2016/17 period $\left[\theta=2.30, \mathrm{R}^{2}=0.1177\right.$, $\left.\mathrm{AIC}=59,284\right]$.
Note: The Year:Area interaction term was not selected.

The final model after adding Year:Area interaction term in the scope of variables for WAG were:
$\ln ($ CPUE $)=$ Year + Captain + Gear + ns $($ Soak, 10 $)+$ Area
for the 1995/96-2004/05 period $\left[\theta=1.00, \mathrm{R}^{2}=0.2031\right.$, $\left.\mathrm{AIC}=196,290\right]$
Note: The Year:Area interaction term was not selected.
$\ln ($ CPUE $)=$ Year + Area + Year: Area $+\mathrm{ns}($ Soak, 5$)$
for the 2005/06-2016/17 period
$\left[\theta=1.17, R^{2}=0.1356\right.$, AIC $=94,273$ with $\mathrm{ns}($ Soak, 5$)$ forced in]
Note: A number of indeterminate parameter values for interaction factors were observed. However, as per January 2018 CPT request, we used the resulting CPUE indices in scenario WAG17_0c.

Figures B. 1 to B. 4 depict the trends in nominal and standardized CPUE indices for the two CPUE time series for EAG and WAG, respectively.

## b. Fishery independent survey CPUE index by GLM:

The fishing industry and ADF\&G cooperative fishery independent surveys have been conducted during the first month of each fishing season (i.e., August) for the last three years, 2015-2017 in the EAG, and this project is expected to continue. The sampling procedure is different from the observer sampling design. Fishing operations are conducted in a randomly selected grids ( 2 km X 2 km ) and five pots per string are sampled for fishery and biological data collection (e.g., date, vessel, captain, soak time, depth, Lat. Long., pot number, string number, species, sex, size, legal status, catch, etc.). There are 7294 records for EAG golden
king crab. For CPUE standardization, these data were further reduced by $5 \%$ cutoff of Soak time and $1 \%$ cutoff of Depth on both ends of the variable range to remove unreliable data or data from dysfunctional pot operations.

The GLM followed the same procedure as that for observer data for standardizing CPUE. Only $R^{2}$ criterion was used for variable selection. The null model was
$\ln \left(\right.$ CPUE $\left._{i}\right)=$ Year $_{y_{i}}$
where Year is a factorial variable.
The maximum set of model terms offered to the stepwise selection procedure was:

$$
\begin{aligned}
& \ln \left(\mathrm{CPUE}_{\mathrm{i}}\right)=\text { Year }_{\mathrm{y}_{\mathrm{i}}}+\mathrm{ns}\left(\text { Soak }_{\text {si }}, \text { df }\right)+\text { Vessel }_{\mathrm{vi}}+\text { Captain }_{\mathrm{ci}}+\text { VesStrPot }_{\mathrm{Si}}+\text { Lat }_{i}+ \\
& \text { LongLong }_{i}+\mathrm{ns}\left(\text { Depth }_{\mathrm{di}}, \text { df }\right) \\
& \text { (B. 18) }
\end{aligned}
$$

where Soak is in unit of days and is numeric; Depth in fathom is a numeric variable; Vessel code, Captain code, VesStrPot , Lat, and Long are factorial variables; ns=cubic spline, and df $=$ degree of freedom. To make a unique factor level for vessel, string, and pot, we concatenated the Vessel code, string ID, and PotID (VesStrPot)..

The final model was
$\ln ($ CPUE $)=$ Year + VesStrPot + Lat + ns $($ Soak, 11)
for the 2015/16-2017/18 period
$\left[\theta=2.30, R^{2}=0.55695, \operatorname{AIC}=30,481\right.$ with $n s($ Soak, 11) forced in $]$.
Because the assessment model considered fisheries data up to 2016/17, we used CPUE indices for 2015/16-2016/17 in the fitting of scenario EAG17_0f.

Figure B. 5 shows the trends in nominal and standardized CPUE indices for the two CPUE time series for the independent survey in EAG.
c. Observer CPUE index by VAST:

We used a spatio-temporal deltaGLMM (Thorson et al., 2015; Thorson et al., 2017; Thorson and Barnett, 2017) to develop separate sets of CPUE indices based on the observer data for the pre-(1995/96-2004/05) and post- rationalization (2005/06-2016/17) periods. This is a two-stage model that first estimates the probability of presence (B.20) then estimates positive catch rates in the second stage (B.21). To account for the spatial dependence of crab density within the model, spatial and spatio-temporal autocorrelation are incorporated into the model as random effects. Positive catch rates in the model are a function of area fished. Since area swept is difficult to define for a pot gear, we used soak time as the area fished proxy. The number of knots is user defined and derived over the spatial domain based on the relative sampling density. Based on the fishing locations recorded during 1995/96-2016/17, one hundred knots were selected for each of EAG and WAG (Thorson et al., 2015; Runnebaum et al., 2017) (Figure B.6).

The final models applied to each period for EAG and WAG data are:
$P_{i}=\operatorname{logit}^{-1}\left[d_{T_{(i)}}^{(p)}+r_{v_{i}}^{(p)}+\omega_{J_{(i)}}^{(p)}+\varepsilon_{J_{(i),}, T_{(i)}}^{(p)}\right]$
$\lambda_{i}=w_{i} \exp \left[d_{T_{(i)}}^{(\lambda)}+r_{v_{i}}^{(\lambda)}+\omega_{J_{(i)}}^{(\lambda)}+\varepsilon_{J_{(i)}, T_{(i)}}^{(\lambda)}\right]$
where
$P_{i}$ and $\lambda_{i}$ are the expected probabilities of an occupied habitat and positive catches given occupied habitat for sample i at a given location; $d_{T_{(i)}}$ is the average annual density in year $T_{(i)}$, $J_{i}$ is the nearest knot to sample $\mathrm{i} ; w_{i}$ is the soak time for sample $\mathrm{i} ; \omega_{J_{(i)}}$ is a random field accounting for spatially correlated variability at knot $J_{(i)}$ that is persistent among years; $\varepsilon_{J_{(i)}, T_{(i)}}$ is the random field accounting for spatio-temporal correlation at knot $J_{(i)}$ in year $T_{(i)}$; and $r_{v_{i}}$ is a random effect accounting for differences in catch between vessels.

Figure B. 7 compares the CPUE index trends between GLM and deltaGLMM estimates for EAG and WAG. The CPUE trends are similar, in particular during the post rationalization period. The confidence intervals for deltaGLMM estimated CPUE indices are wider than those of GLM estimated CPUE indices. Spatio-temporal models have been shown to provide more precision compared to design sampling of stock distribution because they are able to account for the spatial variation in density, thereby minimizing unexplained variability (Thorson et al., 2015). However, this was not the case when using a spatio-temporal deltaGLMM for golden king crab along the Aleutian Islands. There are likely two contributing factors to the increased variability in CPUE estimates. 1) Currently the VAST modeling framework is not able to account for an 'edge effect' when extrapolating species density to a given grid cell. In essence, there is no recognition of a land existing between density distributions, it appears density estimates from a given knot are being extrapolated over land. 2) Standard abundance surveys use a pre-designed grid and sample all grid cells consistently; on the other hand, commercial fishery samples the stock area opportunistically. Consequently, there are some years where there are large gaps in coverage, resulting in large areas being assigned density estimates with no direct observations for that area. This is leading to likely uncertainty in the spatial variability in density estimates. These are the two likely causes of increased variability in standard error estimates when using the deltaGLMM for Aleutian Islands golden king crab.

## Fish Ticket CPUE index:

We also fitted the lognormal GLM for the fish ticket retained CPUE time series 1985/861998/99 offering Year, Month, Vessel, Captain, and Area as explanatory variables. The fitting procedure was similar to that followed for observer data analysis. There were 20,435 records for 1985/86-2016/17. The number of records was reduced by considering only those for 1985/86 1998/99, positive catches, and Vessels with five trips per year for at least three years.

The final model for EAG was:
Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Captain + Area + Vessel + Month, $R^{2}=0.5037$, AIC $=4,957$
Under CAIC selection criteria:
$\ln ($ CPUE $)=$ Year + Vessel + Month, $\mathrm{R}^{2}=0.3700$, AIC $=5,345$
and those for WAG was:
Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Captain + Vessel + Area, $R^{2}=0.4971$, AIC $=9,923$
Under CAIC selection criteria:
$\ln ($ CPUE $)=$ Year + Vessel, $R^{2}=0.3679$, AIC $=10,670$
The final model after adding the Year:Area interaction term in the scope of variables for EAG were:

Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Captain + Area + Vessel + Month + Year: Area, $R^{2}=0.6086$, AIC $=$ 4,783

The final model after adding the Year:Area interaction term in the scope of variables for WAG were:

Under R square selection criteria:
$\ln ($ CPUE $)=$ Year + Captain + Vessel + Area + Year: Area, $R^{2}=0.6105$, AIC $=9,802$

Note:

1. A number of indeterminate parameter values for Year:Area interaction factors were observed. However, as per January 2018 CPT request, we used the resulting CPUE indices in scenarios EAG17_0c and WAG17_0c.
2. The $R^{2}$ values for the fish ticket data fits are much higher compared to that for observer data fits.

Figures B. 8 and B. 9 depict the trends in nominal and standardized CPUE indices for the fish ticket CPUE time series for EAG and WAG, respectively.

Note: For brevity we did not present the diagnostic figures for the fits in this document. They are available with the first author.

Figure B.1. Trends in non-standardized [arithmetic (nominal)] and standardized (negative binomial GLM) CPUE indices with +/-2 SE for Aleutian Islands golden king crab observer data from EAG (east of $174{ }^{\circ} \mathrm{W}$ longitude). Top panel: 1995/96-2004/05, and bottom panel: 2005/06-2016/17. Standardized indices: black line and non-standardized indices: red line. Variable selection by $\mathrm{R}^{2}$ criteria.

Figure B.2. Trends in non-standardized [arithmetic (nominal)] and standardized (negative binomial GLM) CPUE indices with +/- 2 SE for Aleutian Islands golden king crab observer data from EAG (east of $174^{\circ} \mathrm{W}$ longitude). Figure B.7. Comparison of GLM (black) and VAST (green) estimated CPUE indices with +/- 2 SE for Aleutian Islands golden king crab in EAG (top panel) and WAG (bottom panel) for 1995/96-2016/17. GLM variable selection by $\mathrm{R}^{2}$ criteria.

Figure B.8. Trends in non-standardized [arithmetic (nominal)] and standardized (lognormal GLM) CPUE indices with +/- 2 SE for Aleutian Islands golden king crab from EAG. The 1985/86-1998/99 fish ticket data set was used. Standardized indices: black line and nonstandardized indices: red line. Top panel: variable selection by $\mathrm{R}^{2}$ criteria; bottom panel: variable selection by CAIC square criteria.

Figure B.9. Trends in non-standardized [arithmetic (nominal)] and standardized (lognormal GLM) CPUE indices with $+/-2$ SE for Aleutian Islands golden king crab from WAG. The 1985/86-1998/99 fish ticket data set was used. Standardized indices: black line and nonstandardized indices: red line. Top panel: variable selection by $\mathrm{R}^{2}$ criteria; bottom panel: variable selection by CAIC criteria.

## Appendix C: Male maturity

## Male maturity:

## Method:

We used the 1991 EAG pot survey collected 2457 carapace length (mm CL) and chela height (up to one-tenth of a mm CH ) measurements in the EAG and NMFS survey collected 508 same measurements in Bowers Ridge, WAG for male $50 \%$ maturity length determination. We determined the $50 \%$ maturity length outside the assessment model using the 'segmented regression' package available in R ( R Core Team 2017). We used the $50 \%$ maturity length as the break point for categorizing immature and mature crab for mature male biomass (MMB) determination for EAG and WAG.

First we fitted a linear regression model to the data pair using the R package as follows:
$\ln (C H / C L)=\beta_{0}+\beta_{1} C L$
where $\beta_{0}$ and $\beta_{1}$ are regression parameters
The procedure of 'segmented regression' uses maximum likelihood to fit a somewhat different parameterization of the linear model. It can be approximated as
$\ln (C H / C L)=\beta_{0}+\beta_{1} C L+\beta_{2}[\mathrm{CL}-c]+\gamma I[\mathrm{CL}>c]$
where $\beta_{2}$ is a regression parameter and c is the break point. $\gamma I[\mathrm{CL}>c]$ is a dummy variable. When $\mathrm{CL}<\mathrm{c}$, the model reduces to,
$\ln (C H / C L)=\beta_{0}+\beta_{1} C L+\beta_{2}[C L-c]$
The $\gamma$ term is a measure of the distance between the end of the first segment and the beginning of the next. The model converges when $\gamma$ is minimized, thus this method constrains the segments to be (nearly) continuous.

Results:
Table C1. Breakpoint analysis results for EAG:

| Breakpoint <br> Estimate, CL: | 107.015 | Standard <br> (SE): | Error 1.916 |
| :--- | :--- | :--- | :--- |

Meaningful coefficients of the linear terms:

|  | Estimate | SE | t value | $\operatorname{Pr}(>\|t\|)$ |
| :--- | :--- | :--- | :--- | :---: |
| Intercept | -1.60175 | 0.02286 | -70.05 | $<2 \mathrm{e}-16^{* * *}$ |
| CL | 0.00070 | 0.00026 | 2.72 | $0.00657^{* *}$ |
| U1.CL | 0.00424 | 0.00029 | 14.45 | NA |

Signif. codes: 0 '***' $0.001{ }^{\text {'**' }} 0.01^{\prime *}{ }^{*} 0.05{ }^{\prime} .{ }^{\prime} 0.1^{\prime}{ }^{\prime} 1$
Adjusted R-squared: $0.4551, \mathrm{df}=2453$
Thus, the break point estimate of male CL (i.e., $50 \%$ maturity length) $=107.015 \mathrm{~mm}$ CL.

Table C2. Breakpoint analysis results for WAG:

| Breakpoint <br> Estimate, CL: | 107.482 | Standard <br> (SE): | Error | 2.747 |  |
| :--- | :---: | :---: | :---: | :--- | :---: |
| Meaningful coefficients of the linear terms: |  |  |  |  |  |
|  | Estimate | SE | t value | $\operatorname{Pr}(>\mid t)$ |  |
| Intercept | -1.63672 | 0.05592 | -29.271 | $<2 \mathrm{e}-16^{* * *}$ |  |
| CL | 0.00086 | 0.00059 | 1.446 | 0.149 |  |
| U1.CL | 0.00441 | 0.00063 | 7.035 | NA |  |

Signif. codes: 0 '***' $0.001^{\text {'**' }} 0.01^{\text {'*' }} 0.05^{\prime} .{ }^{\prime} 0.1^{\text {' }} 1$
Adjusted R-squared: $0.7389, \mathrm{df}=504$
Thus, the break point estimate of male CL (i.e., $50 \%$ maturity length) $=107.482 \mathrm{~mm}$ CL.

Figures C. 1 and C. 2 provide the segment regression fit to the $\log (\mathrm{CH} / \mathrm{CL})$ vs. CL data pair for EAG and WAG, respectively:

Figure C.1. Segmented linear regression fit to $\ln (\mathrm{CH} / \mathrm{CL})$ vs. CL data of male golden king crab in EAG.

Figure C.2. Segmented linear regression fit to $\ln (\mathrm{CH} / \mathrm{CL})$ vs. CL data of male golden king crab in WAG.

Bootstrap estimate of breakpoint with $95 \%$ confidence limits:
We created 1000 bootstrap samples of the $\ln (\mathrm{CH} / \mathrm{CL})$ and CL pair and fitted the segmented regression to each sample $[\ln (\mathrm{CH} / \mathrm{CL})$ vs CL$]$ and estimated the median and the $95 \%$ confidence interval ( $2.5 \%$ and $97.5 \%$ percentiles of CL of the breakpoints) for EAG and WAG.

Table C.3. Median and $95 \%$ confidence limits of 1000 bootstrap estimates of male maturity by breakpoint analysis of chela height and carapace length data of golden king crab in EAG (1991 data) and WAG (1984 data).

| Males | Median | Lower 95\% <br> Limit | Upper 95\% Limit |
| :--- | :--- | :--- | :--- |
| EAG <br> Maturity Breakpoint <br> (mm CL) | 107.02 | 85.12 | 111.02 |
| WAG |  |  |  |
| Maturity Breakpoint <br> (mm CL) | 107.85 | 103.46 | 126.03 |

We considered one bin above the median maturity size falling bin as the knife edge breakpoint of maturity. Thus all sizes equal and above 111 mmCL were considered to be fully mature and below this size immature for MMB calculation.

## Review of king crab male maturity:

Chelae allometry has been used to determine morphometric male size-at-maturity among a number of king crab (Lithodidae) stocks. Golden king crab provides a better discrimination of chelae height against size at the onset of maturity than other king crab stocks (Somerton and Otto, 1986). Table C. 4 lists the literature reported estimates of size-at-maturity of males and females of different king crab stocks in the northern hemisphere including golden king crab. Breakpoint analysis has been used to estimate maturity on king crabs in majority of cases (Table C. 4 and Webb, 2014).

Table C.4. Review of estimates of male and female size-at-maturity of golden (Lithodes aequispins), blue ( Paralithodes platypus), and red (Paralithodes camtschatica) king crabs by area and stocks. Numbers in parentheses are standard deviations estimated by the bootstrap sampling method.

## Appendix D: Francis and McAllister and Ianelli re-weighting methods

## Stage-1 effective sample size:

We considered number of vessel-days as the initial input annual effective sample sizes (i.e., Stage-1) for retained and total size compositions and number of trips for groundfish discard catch size composition without enforcing any upper limit. The number of vessel-days was calculated using,
Vessel - days $_{t}=$ mean trip $^{\text {day }} \times$ number of trips made by all vessels ${ }_{t}$
The groundfish bycatch of golden king crab comes from bottom trawlers, fish pot, and longlines. Vessel-days are difficult to calculate for the groundfish bycatch and hence we used annual number of trips as the Stage-1 effective sample size. Please note that we did not use the groundfish discard size compositions in any of the scenario's optimization although the predicted effective sample sizes were produced as a byproduct. We refer to the Stage-1 effective samples sizes for the size-composition of the retained catch, total catch, and the groundfish crab bycatch for year t as $\tau_{1, \mathrm{t}}^{r} \tau_{1, \mathrm{t}}^{T}$, and ${ }^{\tau_{1, \mathrm{t}}^{T_{r}}}$ respectively.

We estimated the Stage-2 effective sample sizes iteratively from Stage-1 input effective sample sizes. The reiterated effective sample sizes' subscripts replace 1 by 2.

## Francis' method:

The Francis' (2011) mean length based method [i.e., Francis TA1.8 method, Punt (2017)] uses the following formulas:

Observed mean length for year $t$,
$\overline{l_{t}}=\sum_{i=1}^{n} l_{t, i} \times P_{t, i}$
Predicted mean length for year $t$,
$\hat{\bar{l}_{t}}=\sum_{i=1}^{n} l_{t, i} \times \hat{P}_{t, i}$
Variance of the predicted mean length in year $t$,

$$
\begin{equation*}
\operatorname{var}\left(\hat{\bar{l}}_{t}\right)=\frac{\sum_{i=1}^{n} \hat{P}_{t, i}\left(l_{t, i}-\hat{l}_{t}\right)^{2}}{S_{t}} \tag{D.4}
\end{equation*}
$$

Francis' re-weighting parameter $W$,

$$
\begin{equation*}
W=\frac{1}{\operatorname{var}\left\{\frac{\bar{l}_{t}-\hat{l}_{t}}{\sqrt{\operatorname{var}\left(\hat{l}_{t}\right)}}\right\}} \tag{D.5}
\end{equation*}
$$

where $\widehat{\mathrm{P}}_{\mathrm{t}, \mathrm{i}}$ and $\mathrm{P}_{\mathrm{t}, \mathrm{i}}$ are the estimated and observed proportions of the catch during year t in lengthclass $i, l_{t, i}$ is the mid length of the length-class i during year $t, S_{t}$ is the effective sample size in
year $t, \hat{\bar{I}}_{t}$ and $\overline{l_{t}}$ are predicted and observed mean lengths of the catch during year $t, n$ is the number of length bins, and W is the re-weighting multiplier of Stage- 1 sample sizes.

Francis (2017) suggested that a good stopping criterion for the iteration process is when there are no appreciable changes in the key outputs. Hence, we considered a stopping criterion of no appreciable change ( $<0.01 \%$ ) in W and terminal year MMB (Equation A.27).
$S_{t}$ is related to the initial input (Stage-1) effective sample size according to:

$$
\begin{equation*}
S_{t, i}=W_{i} \tau_{1, t} \tag{D.6}
\end{equation*}
$$

where $S_{t, i}$ is the effective sample size for year $t$ in iteration $i$ and $W_{i}$ is the Francis weight calculated using Equation D. 5 during iteration i.

We did the re-weighting for combined data (for $M$ estimation), individual scenarios, and MMB profiles. For brevity, we provide the iteration process for Francis Stage-2 weight calculation for individual scenarios for EAG and WAG respectively in Table D.1.

## McAllister's and Ianelli's method:

Based on the assumption that the size-composition data are a multinomial sample, McAllister and Ianelli (1997) provided an estimator for the Stage-2 effective sample sizes based on the ratio of the theoretical variance of expected proportions to the actual variance of proportions,

$$
\begin{equation*}
\tau_{2, t}=\frac{\sum_{l} \hat{P}_{t, l}\left(1-\hat{P}_{t, l}\right)}{\sum_{l}\left(P_{t, l}-\hat{P}_{t, l}\right)^{2}} \tag{D.7}
\end{equation*}
$$

McAllister and Ianelli (1997) set the effective sample size for each size-composition data set for eastern Bering Sea yellowfin sole (Limanda aspera) as the arithmetic mean of $\tau_{2, t}$ over years $t$ (i.e., a year-invariant effective sample size) and iterated the model fitting, updating the effective sample sizes, until convergence occurred. Equation D. 7 ignores correlation among the residuals for the catch proportions so likely overestimates effective sample sizes (Francis, 2011). Punt (2015) suggests using the harmonic mean of $\tau_{2, t}$ if the McAllister and Ianelli formula is used. A harmonic mean (constant) multiplier was consequently used to update the effective sample sizes at each iteration of model fitting until convergence occurred; i.e.

$$
\begin{equation*}
\tau_{2, t, i}=\left\{\frac{1}{n_{t}} \sum_{t}\left[\frac{\tau_{2, t, i-1}}{\tau_{2, t, i-1}}\right]^{-1}\right\}^{-1} \tau_{2, t, i-1} \tag{D.8}
\end{equation*}
$$

where $\tau_{2, t, i}$ is the Stage-2 effective sample size for year $t$ in iteration $i\left(\tau_{2, t, 0}=\tau_{1, \mathrm{t}}\right)$ and $\dot{\tau}_{2, t, i}$ is the result of applying Equation D.7. Convergence of the process of setting the Stage-2 effective sample sizes using Equation D. 8 was assessed similar to Francis' procedure, but the weight ( $W$ ) at the final iteration was allowed to reach 1 . We considered this re-weighting process for scenarios EAG17_0e and WAG17_0e (Table D.1).

Table D.1. Iteration process for Stage-2 effective sample size re-weighting multiplier, $W$, by Francis' (scenarios 17b0, 17_0, 17_0a, 17_0b, 17_0c, 17_0d, and 17_0f) and McAllister and Ianelli (scenario 17_0e) methods for retained, total, and groundfish discard catch size compositions of golden king crab for EAG and WAG. Sc. =scenario. Note: For certain scenarios we have done over six iterations, but we provide only the last three iteration results.

## Appendix E: Jittering

Jittering of scenario 17_0 parameter estimates:
We followed the Stock Synthesis approach to do 100 jitter runs of scenarios EAG17_0 and WAG17_0 parameter estimates to use as initial parameter values (as .PIN file in ADMB) to assess model stability and to determine whether a global as opposed to local minima has been found by the search algorithm:

The Jitter factor of 0.3 was multiplied by a random normal deviation $r d e v=N(0,1)$, to a transformed parameter value based upon the predefined parameter:

$$
\begin{equation*}
\text { temp }=0.5 * \text { rdev }^{*} \text { Jitterfactor } * \ln \left(\frac{P_{\max }-P_{\min }+0.0000002}{P_{v a l}-P_{\min }+0.0000001}-1\right), \tag{E.1}
\end{equation*}
$$

with the final jittered initial parameter value back transformed as:

$$
\begin{equation*}
P_{\text {new }}=P_{\min }+\frac{P_{\max }-P_{\min }}{1.0+\exp (-2.0 \text { temp })}, \tag{E.2}
\end{equation*}
$$

where $P_{\text {max }}$ and $P_{\text {min }}$ are upper and lower bounds of parameter search space and $P_{\text {val }}$ is the estimated parameter value before the jittering.

The jitter results are summarized for scenario 17_0 in Tables E. 1 and E. 2 for EAG and WAG, respectively. Almost all runs converged to the highest log likelihood values for EAG. On the other hand, some jitter runs for WAG produced smaller objective function values compared to the base estimate (run 0 ). However, those fits predicted extremely large groundfish bycatches in certain years, consequently we ignored those runs. Thus we selected scenario 17_0 as the base scenario for EAG and WAG.

Table E.1. Results from 100 jitter runs for scenario 17_0 for EAG. Jitter run 0 corresponds to the original optimized estimates. Note: $\mathrm{B}_{\mathrm{MSY}}$ reference points were based on average recruitment for 1986-2016.

Table E.2. Results from 100 jitter runs for scenario 17_0 for WAG. Jitter run 0 corresponds to the original optimized estimates. Since there were differences in the objective function estimates, we sorted out the jitter results from lowest to the highest objective function values. Note: $\mathrm{B}_{\mathrm{MSY}}$ reference points were based on average recruitment for 1986-2017.

| Jitter <br> Run | Objective <br> Function | Maximum Gradient | $\mathrm{B}_{35 \%}$ ( t ) | OFL (t) | Current <br> MMB (t) |

## Appendix F: Projection

Simulations on future projection and outlook of Aleutian Islands golden king crab under Tier 3 harvest control rule

## Simulation Method

We simulated the future male abundances from the 2018 model scenarios 17_0 and 17_0d estimated abundances by length-class and recruitment. We projected the abundances for 30 years with 100 random replicates and estimated various management parameters: legal male biomass (LMB), mature male biomass (MMB), OFL (total) catch, retained catch, CPUE indices, and probability of overfishing under federal overfishing control rule. Future population projections primarily depend on future recruitment, but crab recruitment is difficult to predict. Therefore, annual recruitment for the projections was selected by a random selection from estimated recruitments during 1987-2012 (CPT and SSC agreed time period, Siddeek et al., 2017). Besides recruitment, the other major uncertainty for the projections is estimated abundance in 2016 (terminal year). The estimated recruitments were randomly selected using a uniform random distribution whereas the 2016 abundance was randomized by a lognormal random error.
The simulation steps are as follows:

1) Run the assessment model scenario 17_0 and 17_0d from the start year to the terminal year of the data (1981/82-2016/17 fishing seasons). Model equations are provided in Appendix A.
2) After estimating the abundances and parameters, run the forecast function (at the standard deviation phase of the ADMB optimization).
a) Randomize the recruitment:

Random selection of model estimated recruits for 1987 to 2012 was done as follows:

$$
\begin{equation*}
R_{i}=e^{\left[\operatorname{logMeanRec}+r e c_{\operatorname{dev}(1987+\text { uniform random error selected year incrment })}\right]} \tag{F.1}
\end{equation*}
$$

where $\mathrm{i}=2$ to 30 years
b) Randomize the abundance:

The lognormal random error to abundance is added in the following steps:
We first scaled the standard error based on the terminal year abundance (number of crabs) on its standard error (i.e., $\mathrm{CV}=\frac{\text { Std.Error of terminal year mature male abundance }}{\text { terminal year mature male abundance }}$ ). Then we added the lognormal random error to abundance as follows:
$N_{i}=N_{i} e^{\varepsilon_{i}-\frac{\sigma_{\varepsilon}^{2}}{2}}$
where $\sigma_{\varepsilon}=\frac{\text { Std.Error of terminal year mature male abundance }}{\text { terminal year mature male abundance }}$
$\mathrm{N}=$ abundance, and $i=$ projection year.
The scaled standard error estimates (CV) are:
Scenario 17_0:
WAG: $\sigma_{\varepsilon}=0.18108$
EAG: $\quad \sigma_{\varepsilon}=0.18726$
Scenario 17_0d:
WAG: $\sigma_{\varepsilon}=0.23771$
EAG: $\quad \sigma_{\varepsilon}=0.23674$
3. Projection.

Two scenarios of fishing mortality for the directed pot fishery were used in the projections under Tier 3 control rule (i.e., Federal overfishing control rule):
i) No directed fishery. This was used as a base projection.
ii) $F_{35 \%}$. This is the maximum fishing mortality allowed under the current Tier 3 overfishing definitions.

The groundfish bycatch mortality was kept constant at the last 10-year mean fishing mortality level.

Each scenario was replicated 100 times and projections made over 30 years beginning in 2016
At each time step in the future:
a) Calculated legal male biomass (LMB) and mature male biomass (MMB).
b) Calculated the overfishing level total catch (OFL), acceptable biological catch (ABC), retained catch (RETC), and catch-per-unit effort (CPUE) indices using the Tier 3 OFL control rule.
c) Implemented the fishery under Tier 3 OFL control rule and removed the OFL catch from the simulated population.
d) Drew new recruitment numbers from historical distribution.
e) Updated the number-at-length.
4) Repeated step- 3 for 30 years into the future.
5) Repeated steps 3 and 4 for 100s of Monte Carlo trials, randomizing recruitment and abundance.
6) Used the annual distribution of simulated OFL catch, ABC catch, RETC, CPUE, LMB, and MMB to calculate performance statistics:
a) Median and mean annual MMB, LMB, OFL, ABC, RETC, and CPUE with standard errors and $95 \%$ confidence limits (by Efron's and Tibshirani's (1986) method: $2.5 \%$ and $97.5 \%$ percentile points).
b) Probability that the median MMB remains above the threshold reference points ( $0.25 \mathrm{MMB}_{35 \%}$, 2016), median ABC and median OFL exceeding $\mathrm{ABC}_{2016}$ and $\mathrm{OFL}_{2016}$ respectively during the $30-\mathrm{yr}$ projection period. The subscript 2016 refers to estimates by the respective assessment model scenarios.

The state harvest control rule simulation procedures are under development; therefore, we are not presenting any results of the state harvest strategy in this report.

## Results

The simulations compared the projection outputs for 17_0 and 17_0d scenarios and also investigated the probability of the stock being overfished (median MMB $<0.25 \mathrm{MMB}_{35 \%, 2016}$ ) and overfishing occurred [i.e., median OFL catch (i.e., median total catch under FOFL) exceeded OFL 2016 or $\mathrm{ABC}_{2016}$ estimates] during the 30 yr projection time horizon. The standard deviation of the total catch (OFL), retained catch (RETC), and CPUE are provided to assess the variability of the harvest under Tier 3 control rule.

We provide the results in the subsequent tables for the Tier 3 control rule for both scenarios. Tables F. 1 and F. 2 compare the $30-\mathrm{yr}$ projected OFL catches with that of the model estimated OFL and ABC and provide the probability of overfishing and overfished under Tier 3 control rule for 17_0 and 17_0d scenarios for EAG and WAG, respectively. Subsequent tables (Tables F. 3 to F.14) provide the mean, median, standard deviation, and $95 \%$ confidence intervals for projected OFL, ABC, RETC, CPUE, LMB, and MMB during time horizon. We can make the following general conclusion from the simulation results:

If the Tier 3 control rule were directly applied as the harvest strategy, the probability of median MMB declining below the threshold (overfished) would be zero for both scenarios for EAG and WAG. However, probability of median OFL (total) catch exceeding ABC would be 0.067 for scenario 17_0, but zero for scenario 17_0d for EAG. On the other hand, probability of median OFL exceeding ABC would be 1.0 for both scenarios (17_0 and 17_0d) for WAG (Tables F. 1 and F.2).

Table F.2. Comparison of projected median OFL (i.e., total catch under Tire 3 FofL) with OFL 2016 and $\mathrm{ABC}_{2016}$ in metric tons ( t ) for scenario (Sc) 17_0 and 17_0d with $\mathrm{F}=\mathrm{F}_{35} \%\left(0.6 \mathrm{yr}^{-1}\right.$ and $0.68 \mathrm{yr}^{-1}$ for $\mathrm{Sc} 17 \_0$ and $\mathrm{Sc} 17 \_0 \mathrm{~d}$, respectively) and $\mathrm{F}=0$ for WAG.

Probability of projected median OFL exceeding OFL2016 and $\mathrm{ABC}_{2016}$ and projected median MMB ( t ) depleting below the threshold MMB $_{2016}$ are also listed. Thresh ${ }_{2016}=$ threshold MMB in 2016.

Table F.9. Projected mean, median, and standard deviation (SD) of legal male (LMB) and mature male (MMB) biomass ( t ) with $95 \%$ confidence limits under no directed fishery (top) and under $\mathrm{F}_{35 \%}$ (bottom) harvest control rule for scenario 17_0 for WAG, 2016-2045. The top table provides a base projection scenario with no directed fishery.

Table F.12. Projected mean, median, and standard deviation (SD) of legal male (LMB) and mature male (MMB) biomass ( t ) with $95 \%$ confidence limits under no directed fishery (top) and under $\mathrm{F}_{35 \%}$ (bottom) harvest control rule for scenario 17_0d for WAG, 2016-2045. The top table provides a base projection scenario with no directed fishery.

## Appendix H. B0 Analysis

For proper B0 analysis, a stock-recruitment relationship and impacts of environmental factors on recruitment are needed. We did not establish a stock-recruitment relationship for Aleutian Islands golden king crab. Furthermore, the impacts of environmental factors on recruitment have not been studied in the Aleutian Islands areas. Therefore, we approached the B0 analysis in a simple way. We computed the time series of B0 values using the same recruitment time series estimated by the base assessment model 17_0 and setting all directed and bycatch fishing mortality to zero. Figure H. 1 compares the time series of estimated B0 and MMB with fishing and MMB ratio (MMB/B0) for scenario 17_0 separately for EAG and WAG. It is clear that the fishery has a great impact on the biomass dynamics with MMB dropping precipitously with the onset of significant fishery removals in 1981.

Figure H.1. Estimated B0 (t) (dark green curve) and MMB (t) with fishing (black curve with +/2SE) (top panel ); and MMB/B0 ratio (bottom panel) from 1960 to 2016 for scenario 17_0 for Aleutian Islands golden king crab in EAG (left) and WAG (right). (Note: 2016 MMB= MMB estimated on 15 February 2017).

# 9. Assessment of Pribilof Islands Golden King Crab (PIGKC) [2017] 

Benjamin Daly, ADF\&G, Kodiak
Alaska Department of Fish and Game
Division of Commercial Fisheries
[NOTE: In accordance with the approved schedule, no assessment was conducted for this stock this year, however, a full stock assessment will be conducted in 2020. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018 specifications]

# Pribilof Islands Golden King Crab <br> - 2017 Tier 5 Assessment <br> 2017 Crab SAFE Report Chapter (September 2017) 

Benjamin Daly, ADF\&G, Kodiak<br>Alaska Department of Fish and Game<br>Division of Commercial Fisheries<br>351 Research Ct.<br>Kodiak, AK 99615, USA<br>Phone: (907) 486-1865<br>Email: ben.daly@alaska.gov

## Executive Summary

1. Stock: Pribilof Islands (Pribilof District) golden king crab Lithodes aequispinus

## 2. Catches:

Commercial fishing for golden king crab in the Pribilof District has been concentrated in the Pribilof Canyon. The domestic fishery developed in 1982/83, although some limited fishing occurred at least as early as 1981/82. Peak retained catch occurred in 1983/84 at $388 \mathrm{t}(856,475$ lb ). The fishing season for this stock has been defined as a calendar year (as opposed to 1-July-to-30-June crab fishing year) after 1983/84. Since then, participation in the fishery has been sporadic and annually retained catch has been variable: from $0 \mathrm{t}(0 \mathrm{lb})$ in the ten years that no vessels participated (1984, 1986, 1990-1992, 2006-2009, and 2015) to 155 t ( $341,908 \mathrm{lb}$ ) in 1995, when seven vessels made landings. The fishery is not rationalized. There is no state harvest strategy in regulation. A guideline harvest level (GHL) was first established for the fishery in 1999 at $91 \mathrm{t}(200,000 \mathrm{lb})$. The GHL was reduced to $68 \mathrm{t}(150,000 \mathrm{lb})$ for 2000-2014 and reduced to $59 \mathrm{t}(130,000 \mathrm{lb})$ in 2015 . No vessels participated in the directed fishery and no landings were made during 2006-2009. Catch data from 2003-2005 and 2010-2014 cannot be reported here under the confidentiality requirements of State of Alaska (SOA) statute Sec. 16.05.815. The 2003 and 2004 fisheries were closed by emergency order to manage the retained catch towards the GHL; the 2005 and 2010-2014 fisheries were not closed by emergency order. No vessels participated in the directed fishery during 2015 or 2016. Discarded (non-retained) catch has occurred in the directed golden king crab fishery, the eastern Bering Sea snow crab fishery, the Bering Sea grooved Tanner crab fishery, and in Bering Sea groundfish fisheries. Estimates of annual total fishery mortality during 2001-2016 due to crab fisheries range from 0 t to 73 t , with an average of 24 t . There was no discarded catch during crab fisheries in 2016. Estimates of annual fishery mortality during 1991/92-2016 due to groundfish fisheries range from $<1 \mathrm{t}$ to 9 t , with an average of 2 t (estimates of annually discarded catch during Bering Sea groundfish fisheries are reported for crab fishing years from 1991 to 2008, and by calendar years from 2009 to 2016). Total fishery mortality in groundfish fisheries during the 2016 crab fishing year was 0.24 t .

## 3. Stock biomass:

Stock biomass (all sizes, both sexes) of golden king crab have been estimated for the Pribilof Canyon area using the area-swept technique applied to data obtained from the biennial eastern Bering Sea upper continental slope trawl survey performed by NMFS-AFSC in 2002, 2004, 2008, 2010, 2012, and 2016 (Hoff and Britt 2003, 2005, 2009, 2011; Hoff 2013, 2016). See Appendix A1 for summaries of the slope survey as they pertain to data on and estimates of Pribilof Island golden king crab stock biomass. Complete data on size-sex composition of survey catch are available only from the 2008-2016 biennial surveys (C. Armistead, NMFS-AFSC, Kodiak). Biomass estimates by sex and size class from the 2008, 2010, and 2012 surveys were presented in a May 2013 (Gaeuman 2013a) report to the Crab Plan Team and biomass estimates of mature males from the 2008-2012 biennial surveys were presented in a September 2013 (Gaeuman 2013b) report to the Crab Plan Team. Biomass estimates from the 2016 survey have not been presented to the Crab Plan Team prior to this report.

## 4. Recruitment:

Estimated from size-sex composition data from the eastern Bering Sea upper continental slope trawl survey, mature male biomass in the entire survey area increased slightly from 812 t $(1,790,154 \mathrm{lb})$ in 2012 to $897 \mathrm{t}(1,977,546 \mathrm{lb})$ in 2016 , and from $256 \mathrm{t}(564,383 \mathrm{lb})$ in 2012 to $475 \mathrm{t}(1,047,196 \mathrm{lb})$ in 2016 in the Pribilof canyon.

## 5. Management performance:

No overfished determination (i.e., MSST) has been made for this stock, although approaches to using data from the biennial NMFS-AFSC eastern Bering Sea upper continental slope surveys have been presented to, and considered by, the Crab Plan Team (Gaeuman 2013a, 2013b; Pengilly 2015, Pengilly and Daly 2017; Appendix A1). No vessels participated in the 2015 or 2016 directed fisheries (i.e., retained catch= $0 \mathrm{t} ; 0 \mathrm{lb}$ ) and no bycatch was observed in crab fisheries in these years; 0.24 t of fishery mortality occurred during groundfish fisheries in 2016. Overfishing did not occur in 2016. The GHL for the 2018 season has yet to be established (M.Stichert, ADF\&G, Kodiak, pers. comm., 1 April 2017). The 2018 OFL and ABC in the table below are the author's recommendations, which follow previous determinations.

a. Guideline harvest level, established in lb and converted to t .
b. Total retained catch plus estimated bycatch mortality of discarded catch during crab fisheries and bycatch mortality due to groundfish fisheries are included here, but not for 2013 and 2014 because the directed fishery is confidential.
c. Confidential under Sec. 16.05.815 (SOA statute). GHL not attained.

Management Performance Table (values in millions of lb)

| Calendar <br> Year | MSST | Biomass <br> $(M M B)$ | GHL $^{\text {a }}$ | Retained <br> Catch | Total <br> Catch $^{\text {b }}$ | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2013 | N/A | N/A | 150,000 | Conf. $^{\text {c }}$ | Conf. $^{\text {c }}$ | 0.20 | 0.18 |
| 2014 | N/A | N/A | 150,000 | Conf. $^{\text {c }}$ | Conf. $^{\text {c }}$ | 0.20 | 0.18 |
| 2015 | N/A | N/A | 130,000 | 0 | 0.004 | 0.20 | 0.15 |
| 2016 | N/A | N/A | 130,000 | 0 | $<0.001$ | 0.20 | 0.15 |
| 2017 | N/A | N/A | 130,000 |  |  | 0.20 | 0.15 |
| 2018 | N/A | N/A |  |  |  | 0.20 | 0.15 |

a. Guideline harvest level.
b. Total retained catch plus estimated bycatch mortality of discarded catch during crab fisheries and groundfish fisheries. Estimates of annual bycatch mortality during $1991 / 92-2016$ groundfish fisheries are $\leq 19,480 \mathrm{lb}$, with an average of $5,098 \mathrm{lb}$.
c. Confidential under Sec. 16.05.815 (SOA statute). GHL not attained.
6. Basis for the OFL and ABC: The values for 2018 are the author's recommendation.

| Calendar <br> Year | Tier | Years to define <br> Average catch (OFL) | Natural <br> Mortality | Buffer |
| :---: | :---: | :---: | :---: | :---: |
| 2013 | 5 | $1993-1998^{\mathrm{a}}$ | $0.18 \mathrm{yr}^{-1}$ | $10 \%$ |
| 2014 | 5 | $1993-1998^{\mathrm{a}}$ | $0.18 \mathrm{yr}^{-1}$ | $10 \%$ |
| 2015 | 5 | $1993-1998^{\mathrm{a}}$ | $0.18 \mathrm{yr}^{-1}$ | $25 \%$ |
| 2016 | 5 | $1993-1998^{\mathrm{a}}$ | $0.18 \mathrm{yr}^{-1}$ | $25 \%$ |
| 2017 | 5 | $1993-1998^{\mathrm{a}}$ | $0.18 \mathrm{yr}^{-1}$ | $25 \%$ |
| 2018 | 5 | $1993-1998^{\mathrm{a}}$ | $0.18 \mathrm{yr}^{-1}$ | $25 \%$ |

a. OFL was for total catch and was determined by the average of the annual retained catch for these years multiplied by a factor of 1.052 to account for the estimated bycatch mortality occurring in the directed fishery plus an estimate of the average annual bycatch mortality due to non-directed crab fisheries and groundfish fisheries for the period.
b. Assumed value for FMP king crab in NPFMC (2007); does not enter into OFL estimation for Tier 5 stocks.
7. PDF of the OFL: Sampling distribution of the recommended Tier 5 OFL was estimated by bootstrapping. The standard deviation of the estimated sampling distribution of the recommended OFL (Alternative 1) is $23 \mathrm{t}(\mathrm{CV}=0.25$; section G.1).
8. Basis for the ABC recommendation: A $25 \%$ buffer on the OFL, the default; i.e., $\mathrm{ABC}=(1-0.25) \cdot$ OFL. This is a data-poor stock.
9. A summary of the results of any rebuilding analyses: Not applicable; stock is not under a rebuilding plan.

## A. Summary of Major Changes

1. Changes to the management of the fishery: Fishery continues to be managed under authority of an ADF\&G commissioner's permit; guideline harvest level (GHL) was reduced from $68 \mathrm{t}(150,000 \mathrm{lb})$ to $59 \mathrm{t}(130,000 \mathrm{lb})$ in 2015 to account for bycatch mortality in the directed fishery, non-directed crab fisheries, and groundfish fisheries, and to avoid exceeding the ABC. The GHL remained at $59 \mathrm{t}(130,000 \mathrm{lb})$ in 2016 and 2017. The GHL for the 2018 has yet to be established.
2. Changes to the input data:

- Retained catch and discarded catch data have been updated with the results for the 2016 directed fishery, during which no vessels participated, and bycatch in other crab fisheries in 2016, which was zero.
- Discarded catch estimates from groundfish fisheries have been listed by calendar year from 2009 to 2016, including 0.24 t of bycatch mortality for 2016.

3. Changes to the assessment methodology: This assessment follows the methodology recommended by the CPT since May 2012 and the SSC since June 2012.
4. Changes to the assessment results, including projected biomass, TAC/GHL, total catch (including discard mortality in all fisheries and retained catch), and OFL: The computation of OFL in this assessment follows the methodology recommended by the CPT in May 2012 and the SSC in June 2012 applied to the same data and estimates with the same assumptions that were used for estimating the 2013-2017 Tier 5 OFLs; computations applied directly to data and estimates expressed in metric units resulted in minor changes in results used in previous assessments due to rounding.

## B. Responses to SSC and CPT Comments

- Responses to the most recent two sets of SSC and CPT comments on assessments in general (and relevant to this assessment):
- CPT, May 2016: None pertaining to a Tier 5 assessment.
- SSC, June 2016: None pertaining to a Tier 5 assessment.
- CPT, September 2016: None pertaining to a Tier 5 assessment.
- SSC, October 2015: None.
- Responses to the most recent two sets of SSC and CPT comments specific to the assessment:
- CPT, May 2016:
- "A Tier 4 assessment based on a random effects model was presented at the September 2015 meeting. Information on mature and legal male biomass from the slope trawl surveys was only available for three years (2008, 2010, and 2012), and the model runs did not appear to be able to estimate a process error term with the available data. A slope trawl survey is planned for the summer of 2016 and the CPT will re-evaluate the model with the new survey results in January or May 2017. $\qquad$ "
- Response: The author has conducted the preliminary model analysis with the 2016 survey included, and includes those results in an updated discussion paper.
- SSC, June 2016:
- "In June 2015, the SSC requested that the author approach the harvester about whether they would voluntarily allow confidential data to be presented in assessments. However, this was not done. The SSC reiterates this request."
- Still not done. No participation in the directed fishery since 2014. Waivers have been obtained from harvesters for the confidential seasons and discussions are in progress as to which processor waivers are needed (M. Westphal, ADF\&G, Dutch Harbor, pers. comm., 14 April 2017).
- "Finally, the SSC reiterates last year's request for NMFS to assess the feasibility to provide groundfish PSC data for PIGKC by calendar year".
- Groundfish bycatch data for PIGKC is provided by NMFS-AFSC by calendar year from 2009 to 2016, and is included in this assessment.
- "A Tier 4 assessment based on a random effects model was presented to the CPT in September 2015, but it was unable to estimate process error. That Tier 4 assessment was based on 5 years of slope trawl surveys. The plan is to reevaluate the random effects model after results from the 2016 slope trawl survey become available in 2017. The SSC looks forward to a future Tier 4 assessment."
- Not done. The author re-ran the model with 2016 slope survey data and presents results in an associated discussion paper. However, the author does not present this in relation to a Tier 4 or modified Tier 5 assessment.
- CPT, September 2015 and 2016:
- "The CPT recommends the random effects model be re-evaluated after results from the 2016 slope survey are available."
- Response: See above.
- SSC, October 2015:
- "The SSC concurs with the CPT recommendation" ["that the random effects model be re-evaluated after results from the 2016 slope survey are available"]
- Response: Okay. See above.

## C. Introduction

1. Scientific name: Lithodes aequispinus J. E. Benedict, 1895
2. Description of general distribution:

General distribution of golden king crab:

Golden king crab, also called brown king crab, range from Japan to British Columbia. In the BSAI, golden king crab are found at depths from 200 m to $1,000 \mathrm{~m}$, generally in high-relief habitat such as inter-island passes (NMFS 2004).

Golden, or brown, king crab occur from the Japan Sea to the northern Bering Sea (ca. $61^{\circ} \mathrm{N}$ latitude), around the Aleutian Islands, on various sea mounts, and as far south as northern British Columbia (Alice Arm) (Jewett et al. 1985). They are typically found on the continental slope at depths of $300-1,000 \mathrm{~m}$ on extremely rough bottom, and are frequently found on coral (NMFS 2004, pages 3-43).

The Pribilof District is part of king crab Registration Area Q (Figure 1). Leon et al. (2017) define those boundaries:

> The Bering Sea king crab Registration Area Q southern boundary is a line from $54^{\circ} 36^{\prime} \mathrm{N}$ lat, $168^{\circ} \mathrm{W}$ long, to $54^{\circ} 36^{\prime} \mathrm{N}$ lat, $171^{\circ} \mathrm{W}$ long, to $55^{\circ} 30^{\prime} \mathrm{N}$ lat, $171^{\circ} \mathrm{W}$ long, to $55^{\circ} 30^{\prime} \mathrm{N}$ lat, $173^{\circ} 30^{\prime} \mathrm{E}$ long. The northern boundary is the latitude of Point Hope ( $68^{\circ} 21^{\prime} \mathrm{N}$ lat). The eastern boundary is a line from $54^{\circ} 36^{\prime} \mathrm{N}$ lat, $168^{\circ} \mathrm{W}$ long, to $58^{\circ} 39^{\prime} \mathrm{N}$ lat, $168^{\circ} \mathrm{W}$ long, to Cape Newenham ( $58^{\circ} 39^{\prime} \mathrm{N}$ lat). The western boundary is the United States-Russia Maritime Boundary Line of 1990 (Figure 24). Area Q is divided into 2 districts: the Pribilof District, which includes waters south of Cape Newenham; and the Northern District, which includes all waters north of Cape Newenham.

The NMFS-AFSC conducted an eastern Bering Sea continental slope trawl survey on a biennial schedule during 2002-2016 (the 2014 survey was cancelled). Biomass estimates from the 2016 slope survey have not been presented to the Crab Plan Team prior to this document. Results of this survey from 2002-2016 show that the biomass, number, and density (in number per area and in weight per area) of golden king crab on the eastern Bering Sea continental slope are higher in the southern areas than in the northern areas (Gaeuman 2013a, 2013b; Haaga et al. 2009; Hoff 2013, 2016; Hoff and Britt 2003, 2005, 2009, 2011; Pengilly 2015; Pengilly and Daly 2017). Of the six survey subareas (see Figure 1 in Hoff 2016), biomass and abundance of golden king crab were estimated through 2016 to be highest in the Pribilof Canyon area (survey subarea 2), and most of the commercial fishery catches for golden king crab have occurred there (Neufeld and Barnard 2003; Barnard and Burt 2004, 2006; Burt and Barnard 2005, 2006; Leon et al. 2017).

Results of the 2002-2016 biennial NMFS-AFSC eastern Bering Sea continental slope trawl surveys showed that a majority of golden king crab on the eastern Bering Sea continental slope occurred in the 200-400 m and 400-600 m depth ranges (Hoff and Britt 2003, 2005, 2009, 2011; Haaga et al. 2009; Hoff 2013, 2016). Commercial fishing for golden king crab in the Bering Sea typically occurs at depths of 100-300 fathoms (183-549 m; Barnard and Burt 2004, 2006; Burt and Barnard 2005, 2006; Gaeuman 2011, 2013c, 2014; Neufeld and Barnard 2003); average depth of pots fished in the 2002 Pribilof District golden king crab fishery (the most recently prosecuted fishery for which fishery observer data are not confidential) was 214 fathoms (391 $\mathrm{m})$.

## 3. Evidence of stock structure:

Although highest densities of golden king crab are found in the deep canyons of the eastern Bering Sea continental slope, golden king crab occur sporadically on the surveyed slope at locations between those canyons in the eastern Bering Sea (Hoff and Britt 2003, 2005, 2009, 2011; Gaeuman 2013b, 2014; Hoff 2013, 2016). Stock structure within the Pribilof District has not been evaluated. Fishery and slope survey data suggest that areas at the northern and southern border of the Pribilof District are largely devoid of golden king crab (Pengilly 2015, Pengilly and Daly 2017; Appendix A1), but the stock relationship between golden king crab within and outside of the Pribilof District has not been evaluated.
4. Description of life history characteristics relevant to stock assessments (e.g., special features of reproductive biology):
The following review of molt timing and reproductive cycle of golden king crab is adapted from Watson et al. (2002):

Unlike red king crab, golden king crab may have an asynchronous molting cycle (McBride et al. 1982; Otto and Cummiskey 1985; Sloan 1985; Blau and Pengilly 1994). In a sample of male golden king crab $95-155-\mathrm{mm}$ CL and female golden king crab $104-157-\mathrm{mm}$ CL collected from Prince William Sound and held in seawater tanks, Paul and Paul (2000) observed molting in every month of the year, although the highest frequency of molting occurred during May-October. Watson et al. (2002) estimated that only $50 \%$ of $139-\mathrm{mm}$ CL male golden king crab in the eastern Aleutian Islands molt annually and that the intermolt period for males $\geq 150-\mathrm{mm}$ CL averages $>1$ year.

Female lithodids molt before copulation and egg extrusion (Nyblade 1987). From observations on embryo development in golden king crab, Otto and Cummiskey (1985) suggested that time between successive ovipositions was roughly twice that of embryo development and that spawning and molting of mature females occurs approximately every two years. Sloan (1985) also suggested a reproductive cycle $>1$ year with a protracted barren phase for female golden king crab. Data from tagging studies on female golden king crab in the Aleutian Islands are generally consistent with a molt period for mature females of two years or less and that females carry embryos for less than two years with a prolonged period in which they remain in barren condition (Watson et al. 2002). From laboratory studies of golden king crab collected from Prince William Sound, Paul and Paul (2001b) estimated a 20 -month reproductive cycle with a 12 -month clutch brooding period.

Numerous observations on clutch and embryo condition of mature female golden king crab captured during surveys have been consistent with asynchronous, aseasonal reproduction (Otto and Cummiskey 1985; Hiramoto 1985; Sloan 1985; Somerton and Otto 1986; Blau and Pengilly 1994; Blau et al. 1998; Watson et al. 2002). Based on data from Japan (Hiramoto and Sato 1970), McBride et al. (1982) suggested that spawning of golden king crab in the Bering Sea and Aleutian Islands occurs predominately during the summer and fall.

The success of asynchronous and aseasonal spawning of golden king crab may be facilitated by fully lecithoatrophic larval development (i.e., the larvae can develop successfully to juvenile crab without eating; Shirley and Zhou 1997).

Current knowledge of reproductive biology and maturity of male and female golden king crab was reviewed by Webb (2014).

Note that asynchronous, aseasonal molting and the prolonged intermolt period (>1 year) of mature female and the larger mature male golden king crab likely makes scoring shell conditions very difficult and especially difficult to relate to "time post-molt," posing problems for inclusion of shell condition data into assessment models.

## 5. Brief summary of management history:

A complete summary of the management history through 2015 is provided in Leon et al. (2017).
The first domestic harvest of golden king crab in the Pribilof District was in 1981/82 when two vessels fished. Peak retained catch and participation occurred in 1983/84 at a retained catch of $388 \mathrm{t}(856,475 \mathrm{lb})$ landed by 50 vessels (Tables 1a and 1b). Since 1984; the fishery has been managed with a calendar-year fishing season under authority of a commissioner's permit and landings and participation have been low and sporadic. Retained catch since 1984 has ranged from $0 \mathrm{t}(0 \mathrm{lb})$ to $155 \mathrm{t}(341,908 \mathrm{lb})$, and the number of vessels participating annually has ranged from 0 to 8. No vessels fished in 2006-2009, 2015, and 2016, one vessel fished in each of 2010 and 2012-2014, and two vessels fished in 2011.

The fishery is not rationalized and has been managed inseason to a guideline harvest level (GHL) since 1999. The GHL for 1999 was $91 \mathrm{t}(200,000 \mathrm{lb})$, whereas the GHL for 2000-2014 was $68 \mathrm{t}(150,000 \mathrm{lb})$. Following the reduction of ABC from 82 t for 2014 to 68 t for 2015, the GHL was reduced in 2015 to $59 \mathrm{t}(130,000 \mathrm{lb})$.

Catch statistics for 2003-2005 and 2010-2014 are confidential under Sec. 16.05.815 of SOA statutes. It can be noted, however, that the 2003 and 2004 fisheries were closed by emergency order to manage the fishery retained catch towards the GHL, whereas the 2005 and 2010-2014 fisheries were not closed by emergency order. With regard to 2004, "Catch rates during the 2004 fishery were among the highest on record, and the fishery was the shortest ever at approximately three weeks in duration" (Bowers et al. 2005).

A summary of relevant fishery regulations and management actions pertaining to the Pribilof District golden king crab fishery is provided below.

Only males of a minimum legal size may be retained. By State of Alaska regulation (5 AAC 34.920 (a)), the minimum legal size limit for Pribilof District golden king crab is 5.5 -inches (140 mm ) carapace width ( CW ), including spines. A carapace length (CL) $\geq 124 \mathrm{~mm}$ is used to identify legal-size males when CW measurements are not available (Table 3-5 in NPFMC 2007). Golden king crab may be commercially fished only with king crab pots (as defined in 5 AAC 34.050); pots used to take golden king crab in Registration Area Q (Bering Sea) may be longlined (5 AAC 34.925(f)). Pots used to fish for golden king crab in the Pribilof District must have at least four escape rings of no less than five and one-half inches inside diameter installed
on the vertical plane or at least one-third of one vertical surface of the pot composed of not less than nine-inch stretched mesh webbing to permit escapement of undersized golden king crab (5 AAC 34.925 (c)). The sidewall "...must contain an opening equal to or exceeding 18 inches in length... The opening must be laced, sewn, or secured together by a single length of untreated, 100 percent cotton twine, no larger than 30 thread." (5 AAC 39.145(1)). There is a pot limit of 40 pots for vessels $\leq 125$-feet LOA and of 50 pots for vessels $>125$-feet LOA ( 5 AAC 34.925 (e)(1)(B)). Golden king crab can be harvested from 1 January through 31 December only under conditions of a permit issued by the commissioner of ADF\&G (5 AAC 34.910 (b)(3)). Since 2001, those conditions have included the carrying of a fisheries observer.

## D. Data

1. Summary of new information:
2. Retained catch and estimated discarded catch during the 2016 directed fishery (no effort and no catch), estimated discarded catch during other crab fisheries in 2016 (no catch), and the estimated discarded catch in groundfish fisheries during 2016 have been added.

## 2. Data presented as time series:

a. Total catch and b. Information on bycatch and discards:

- The 1981/82-1983/84, 1984-2016 time series of retained catch (number and weight of crab, including deadloss), effort (vessels and pot lifts), average weight of landed crab, average carapace length of landed crab, and CPUE (number of landed crab captured per pot lift) are presented in Tables 1a and 1 b .
- The 1993-2016 time series of weight of retained catch and estimated weight of discarded catch and estimated weight of fishery mortality of Pribilof golden king crab during the directed fishery and all other crab fisheries are given in Table 2. Discarded catch of Pribilof golden king crab occurs mainly in the directed golden king crab fishery, when prosecuted, and to a lesser extent in the Bering Sea snow crab fishery and the Bering Sea grooved Tanner crab fishery when prosecuted. Because the Bering Sea snow crab fishery is largely prosecuted between January and May and the Bering Sea grooved Tanner crab fishery is prosecuted with a calendar year season, discarded catch in the crab fisheries can be estimated on a calendar year basis to align with the calendar-year season for Pribilof District golden king crab. Observer data on size distributions and estimated catch numbers of discarded catch were used to estimate the weight of discarded catch of golden king crab by applying a weight-at-length estimator (see below). Observers were first deployed to collect discarded catch data during the Pribilof District golden king crab fishery in 2001 and during the Bering Sea grooved Tanner crab fishery in 1994. Retained catch or observer data are confidential for at least one of the crab fisheries in 1999-2001, 2003-2005, and 2010-2014. Following Siddeek et al. (2014), the bycatch mortality rate of golden king crab captured and discarded during Aleutian Islands golden king crab fishery was assumed to be 0.2 . Following Foy (2013), bycatch mortality rate of king crab during the snow crab fishery was assumed to be 0.5 . The bycatch mortality rate during the grooved Tanner crab fishery was also assumed to be 0.5 .
- The groundfish fishery discarded catch data are grouped into crab fishery years from 1991/92-2008/09, and by calendar years from 2009-2016. The 1991/92-2016 time series of estimated annual weight of discarded catch and total fishery mortality of golden king
crab during federal groundfish fisheries by gear type (combining pot and hook-and-line gear as a single "fixed gear" category and combining non-pelagic and pelagic trawl gear as a single "trawl" category) is provided in Table 3. Following Foy (2013), the bycatch mortality of king crab captured by fixed gear during groundfish fisheries was assumed to be 0.5 and of king crab captured by trawls during groundfish fisheries was assumed to be 0.8. Data from 1991/92-2008/09 are from federal reporting areas 513, 517, and 521, whereas the data from 2009-2016 are from the State statistical areas falling within the Pribilof District.
- Table 4 summarizes the available data on retained catch weight and the available estimates of discarded catch weight.
c. Catch-at-length: Not used in a Tier 5 assessment; none are presented.
d. Survey biomass estimates: Survey biomass estimates are not used in a Tier 5 assessment. However, see Appendix A1 for biomass estimates of mature male golden king crab using data from the 2002-2016 NMFS-AFSC eastern Bering Sea upper continental slope trawl survey.
e. Survey catch at length: Survey catch at length data are not used in a Tier 5 assessment. However, see Appendix A1 for size data composition by sex of golden king crab during the 2002-2016 Bering Sea upper continental slope trawl surveys.

## f. Other data time series: None.

3. Data which may be aggregated over time:
a. Growth-per-molt; frequency of molting, etc. (by sex and perhaps maturity state):

The author is not aware of data on growth per molt collected from golden king crab in the Pribilof District. Growth per molt of juvenile golden king crab, $2-35 \mathrm{~mm}$ CL, collected from Prince William Sound have been observed in a laboratory setting and equations describing the increase in CL and intermolt period were estimated from those observations (Paul and Paul 2001a); those results are not provided here. Growth per molt has also been estimated from golden king crab with $\mathrm{CL} \geq 90 \mathrm{~mm}$ that were tagged in the Aleutian Islands and recovered during subsequent commercial fisheries (Watson et al. 2002); those results are not presented here because growth-per-molt information does not enter into a Tier 5 assessment.

See section C. 4 for discussion of evidence that mature female and the larger male golden king crab exhibit asynchronous, aseasonal molting and a prolonged intermolt period (>1 year).

## b. Weight-at length or weight-at-age (by sex):

Parameters (A and B) used for estimating weight (g) from carapace length (CL, mm) of male and female golden king crab according to the equation, Weight $=\mathrm{A}^{*} \mathrm{CL}^{\mathrm{B}}$ (from Table 3-5, NPFMC 2007) are: $\mathrm{A}=0.0002988$ and $\mathrm{B}=3.135$ for males and $\mathrm{A}=0.0014240$ and $\mathrm{B}=2.781$ for females.

## c. Natural mortality rate:

The default natural mortality rate assumed for king crab species by NPFMC (2007) is $\mathrm{M}=0.18$. Note, however, natural mortality was not used for OFL estimation because this stock belongs to Tier 5.
4. Information on any data sources that were available, but were excluded from the assessment:

- Standardized bottom trawl surveys to assess the groundfish and invertebrate resources of the eastern Bering Sea upper continental slope were performed in 2002, 2004, 2008, 2010, 2012, and 2016 (Hoff and Britt 2003, 2005, 2009, 2011; Haaga et al. 2009, Gaeuman 2013a, 2013b; Hoff 2016). Data and analysed results pertaining to golden king crab from the 2008-2016 EBS upper continental slope surveys are provided in Appendix A1, but are not used in this Tier 5 assessment.
- Data on the size and sex composition of retained catch and discarded catch of Pribilof District golden king crab during the directed fishery and other crab fisheries are available but are not presented in this Tier 5 assessment.

## E. Analytic Approach

1. History of modeling approaches for this stock:

Gaeuman (2013a, 2013b) and Pengilly (2015) presented assessment-modelling approaches for this stock to the Crab Plan Team using data from the biennial NMFS EBS continental slope survey. However, following the cancellation of the 2014 slope survey, this stock continued to be managed as a Tier 5 stock for 2017, as had been recommended by NPFMC (2007) and by the CPT and SSC in 2008-2017.
2. Model Description: Subsections a-i are not applicable to a Tier 5 sock.

Only an OFL and ABC is estimated for Tier 5 stocks, where "the OFL represent[s] the average retained catch from a time period determined to be representative of the production potential of the stock" (NPFMC 2007). Although NPFMC (2007) defined the OFL in terms of the retained catch, total-catch OFLs may be considered for Tier 5 stocks for which non-target fishery removal data are available (Federal Register/Vol. 73, No. 116, 33926). The CPT (in May 2010) and the SSC (in June 2010) endorsed the use of a total-catch OFL to establish the OFL for this stock. This assessment recommends - and only considers - use of a total-catch OFL for 2018.

Additionally, NPFMC (2007) states that for estimating the OFL of Tier 5 stocks, "The time period selected for computing the average catch, hence the OFL, should be based on the best scientific information available and provide the required risk aversion for stock conservation and utilization goals." Given that a total-catch OFL is to be used, alternative configurations for the Tier 5 model are limited to: 1) alternative time periods for computing the average total-catch mortality; and 2) alternative approaches for estimating the discarded catch component of the total catch mortality during that period.

With regard to choosing from alternative time periods for computing average annual catch to compute the OFL, NPFMC (2007) suggested using the average retained catch over the years 1993 to 1999 as the estimated OFL for Pribilof District golden king crab. Years post-1984 were chosen based on an assumed 8-year lag between hatching and growth to legal size after the

1976/77 "regime shift". With regard to excluding data from years 1985 to 1992 and years after 1999, NPFMC (2007) states, "The excluded years are from 1985 to 1992 and from 2000 to 2005 for Pribilof Islands golden king crab when the fishing effort was less than $10 \%$ of the average or the GHL was set below the previous average catch." In 2008 the CPT and SSC endorsed the approach of estimating OFL as the average retained catch during 1993-1999 for setting a retained-catch OFL for 2009. However, in May 2009 the CPT set a retained-catch OFL for 2010, but using the average retained catch during 1993-1998; 1999 was excluded because it was the first year that a preseason GHL was established for the fishery. In May 2010, the CPT established a total-catch OFL computed as a function of the average retained catch during 19931998, a ratio-based estimate of the bycatch mortality during the directed fishery of that period, and an estimate of the "background" bycatch mortality due to other fisheries. Other time periods, extending into years post-1999, had been considered for computing the average retained catch in the establishment of the 2009, 2010, and 2011 OFLs, but those time periods were rejected by the CPT and the SSC. Hence the period for calculating the retained-catch portion of the Tier 5 totalcatch OFL for this stock has been firmly established by the CPT and SSC at 1993-1998 (the CPT said "this freezes the time frame..."). For the 2012 and the 2013 OFLs, the CPT and SSC recommended the period 2001-2010 for calculating the ratio-based estimate of the bycatch mortality during the 1993-1998 directed fishery, the period 1994-1998 for calculating the estimated bycatch mortality due to non-directed crab fisheries during 1993-1998, and the period 1992/93-1998/99 for calculating the estimated bycatch mortality due to groundfish fisheries during 1993-1998.

Two alternative approaches for determination of the 2013 OFL were presented to the CPT and SSC in May-June 2013. Alternative 1 was the status quo approach (i.e., the approach used to establish the 2012 total-catch OFL). Alternative 2 was the same as Alternative 1 except that it used updated discarded catch data from crab fisheries in 2011. Alternative 2 was presented specifically to allow the CPT and the SSC to clarify whether the 2013 and subsequent OFLs should be computed using data collected after 2010, or if the time periods for data used to calculate the 2013 and subsequent OFLs should be "frozen" at the years used to calculate the 2012 OFL. The CPT and the SSC both recommended Alternative 1, clarifying that Tier 5 OFLs for future years should be computed using only data collected through 2010. Following that recommendation from CPT and the SSC, only one alternative was presented for computing the 2014-2017 Tier 5 OFLs (i.e., the Alternative 1 that was presented in 2013). The 2018 Tier 5 OFL recommended here uses the same approach as used for the 2013-2017 Tier 5 OFLs.

## 3. Model Selection and Evaluation:

## a. Description of alternative model configurations

The recommended OFL is set as a total-catch OFL using 1993-1998 to compute average annual retained catch, an estimate of the ratio of bycatch mortality to retained catch during the directed fishery, an estimate of the average annual bycatch mortality due to the non-directed crab fisheries during 1994-1998, and an estimate of average annual bycatch mortality due to the groundfish fisheries during 1992/93-1998/99; i.e.,

$$
\mathrm{OFL}_{2018}=\left(1+\mathrm{R}_{2001-2010}\right) * \mathrm{RET}_{1993-1998}+\mathrm{BM}_{\mathrm{NC}, 1994-1998}+\mathrm{BM}_{\mathrm{GF}, 92 / 93-98 / 99}
$$

where,

- $\mathrm{R}_{2001-2010}$ is the average of the estimated annual ratio of bycatch mortality to retained catch in the directed fishery during 2001-2010
- $\mathrm{RET}_{1993-1998}$ is the average annual retained catch in the directed crab fishery during 19931998
- $\mathrm{BM}_{\mathrm{NC}, 1994-1998}$ is the estimated average annual bycatch mortality in non-directed crab fisheries during 1994-1998
- $\mathrm{BM}_{\mathrm{GF}, 92 / 93-98 / 99}$ is the estimated average annual bycatch mortality in groundfish fisheries during 1992/93-1998/99.

The average of the estimated annual ratio of bycatch mortality to retained catch in the directed fishery during 2001-2010 is used as a factor to estimate bycatch mortality in the directed fishery during 1993-1998 because, whereas there are no data on discarded catch for the directed fishery during 1993-1998, there are such data from the directed fishery during 2001-2010 (excluding 2006-2009, when there was no fishery effort).

There are no discarded catch data available for the non-directed fisheries during 1993, thus 1994-1998 is used to estimate average annual bycatch mortality in non-directed fisheries.

The estimated average annual bycatch mortality in groundfish fisheries during 1992/93-1998/99 is used to estimate the average annual bycatch mortality in groundfish fisheries during 19931998 because 1992/93-1998/99 is the shortest time period of crab fishery years that encompasses calendar years 1993-1998.

Statistics on the data and estimates used to calculate RET $_{1993-1998}, \mathrm{R}_{2001-2010}, \mathrm{BM}_{\mathrm{NC}, 1994-1998}$, and $\mathrm{BM}_{\mathrm{GF}, 93 / 94-98 / 99}$ are provided in Table 5; the column means in Table 5 are the calculated values of $\mathrm{RET}_{1993-1998}, \mathrm{R}_{2001-2010}, \mathrm{BM}_{\mathrm{NC}, 1994-1998}$, and $\mathrm{BM}_{\mathrm{GF}, 93 / 94-98 / 99 \text {. Using the calculated values of }}$ $\mathrm{RET}_{1993-1998}, \mathrm{R}_{2001-2010}, \mathrm{BM}_{\mathrm{NC}, 1994-1998}$, and $\mathrm{BM}_{\mathrm{GF}, 93 / 94-98 / 99}$, the calculated value of $\mathrm{OFL}_{2018}$ is,

$$
\mathrm{OFL}_{2018}=(1+0.052)^{*} 78.80 \mathrm{t}+6.09 \mathrm{t}+3.79 \mathrm{t}=93 \mathrm{t}(204,527 \mathrm{lbs}) .
$$

b. Show a progression of results from the previous assessment to the preferred base model by adding each new data source and each model modification in turn to enable the impacts of these changes to be assessed: See the table, below.

| Model | Retained- <br> vs. <br> Total-catch | Time Period | Resulting OFL <br> (t) |  |
| :--- | :---: | :---: | :---: | ---: |
| Recommended/status quo | Total-catch | $1993-1998$ |  | 93 |

This is recommended as being the best approach with the limited data available and follows the advice of the CPT and SSC to "freeze" the period for calculation of the OFL at the time period that was established for the 2012 OFL and uses the computations recommended by the CPT and SSC in 2013.
c. Evidence of search for balance between realistic (but possibly over-parameterized) and simpler (but not realistic) models: See Section E, above.
d. Convergence status and convergence criteria for the base-case model (or proposed basecase model): Not applicable.
e. Table (or plot) of the sample sizes assumed for the compositional data: Not applicable.
f. Do parameter estimates for all models make sense, are they credible?:

The time period used for determining the OFL was established by the SSC in June 2012. Retained catch data come from fish tickets and annual retained catch is considered a known (not estimated) value. Estimates of discarded catch from crab fisheries data are generally considered credible (e.g., Byrne and Pengilly 1998; Gaeuman 2011, 2013c, 2014), but may have greater uncertainty in a small, low effort fishery such as the Pribilof golden king crab fishery. Estimates of bycatch mortality are estimates of discarded catch times an assumed bycatch mortality rate. The assumed bycatch mortality rates (i.e., 0.2 for crab fisheries, 0.5 for fixed-gear groundfish fisheries, and 0.8 for trawl groundfish fisheries) have not been estimated from data.
g. Description of criteria used to evaluate the model or to choose among alternative models, including the role (if any) of uncertainty: See section E.3.c, above.
h. Residual analysis (e.g. residual plots, time series plots of observed and predicted values or other approach): Not applicable.
i. Evaluation of the model, if only one model is presented; or evaluation of alternative models and selection of final model, if more than one model is presented: See section E.3.c, above.
4. Results (best model(s)):
a. List of effective sample sizes, the weighting factors applied when fitting the indices, and the weighting factors applied to any penalties: Not applicable.
b. Tables of estimates (all quantities should be accompanied by confidence intervals or other statistical measures of uncertainty, unless infeasible; include estimates from previous SAFEs for retrospective comparisons): See Tables 2-5.
c. Graphs of estimates (all quantities should be accompanied by confidence intervals or other statistical measures of uncertainty, unless infeasible): Information requested for this subsection is not applicable to a Tier 5 stock.
d. Evaluation of the fit to the data: Not applicable for Tier 5 stock.
e. Retrospective and historic analyses (retrospective analyses involve taking the "best" model and truncating the time-series of data on which the assessment is based; a historic analysis involves plotting the results from previous assessments): Not applicable for Tier 5 stock.
f. Uncertainty and sensitivity analyses (this section should highlight unresolved problems and major uncertainties, along with any special issues that complicate scientific assessment, including questions about the best model, etc.): For this assessment, the major uncertainties are:

- Whether the time period is "representative of the production potential of the stock" and if it serves to "provide the required risk aversion for stock conservation and utilization goals", or whether any such time period exists.
- Only a period of 6 years is used to compute the OFL, 1993-1998. The SSC has noted its uneasiness with that situation (" 6 years of data are very few years upon which to base these catch specifications." June 2011 SSC minutes).
- No data on discarded catch due to the directed fishery are available from the period used to compute the OFL.
- Estimation of the OFL rests on the assumption that data on the ratio of discarded catch to retained catch from post- 2000 can be used to accurately estimate that ratio in 1993-1998.
- The bycatch mortality rates used in estimation of total catch.
- Bycatch mortality is unknown and no data that could be used to estimate the bycatch mortality of this stock are known to the author. Hence, only the values that are assumed for other BSAI king crab stock assessments are considered in this assessment. The estimated OFL increases (or decreases) relative to the bycatch mortality rates assumed: doubling the assumed bycatch mortality rates increases the OFL estimate by a factor of 1.15 ; halving the assumed bycatch mortality rates decreases the OFL estimate by a factor of 0.92.

## F. Calculation of the OFL

1. Specification of the Tier level and stock status level for computing the OFL:

- Recommended as Tier 5, total-catch OFL estimated by estimated average total catch over a specified period.
- Recommended time period for computing retained-catch OFL: 1993-1998.
- This is the same time period that was used to establish OFL for 2010-2017. The time period 1993-1998 provides the longest continuous time period through 2016 during which vessels participated in the fishery, retained-catch data can be retrieved that are not confidential, and the retained catch was not constrained by a GHL. Data on discarded catch contemporaneous with 1993-1998 to the extent possible are used to calculate the total-catch OFL.

2. List of parameter and stock size estimates (or best available proxies thereof) required by limit and target control rules specified in the fishery management plan: Not applicable for Tier 5 stock.

## 3. Specification of the total-catch OFL:

a. Provide the equations (from Amendment 24) on which the OFL is to be based:

From Federal Register / Vol. 73, No. 116, page 33926, "For stocks in Tier 5, the overfishing level is specified in terms of an average catch value over an historical time period, unless the Scientific and Statistical Committee recommends an alternative value based on the best available scientific information." Additionally, "For stocks where nontarget fishery removal data are available, catch includes all fishery removals, including retained catch and discard losses. Discard losses will be determined by multiplying the appropriate handling mortality rate by observer estimates of bycatch discards. For stocks where only retained catch information is available, the overfishing level is set for and compared to the retained catch" (FR/Vol. 73, No. 116, 33926). That compares with the specification of NPFMC (2007) that the OFL "represent[s] the average retained catch from a time period determined to be representative of the production potential of the stock."
b. Basis for projecting MMB to the time of mating: Not applicable for Tier 5 stock.
c. Specification of $\mathrm{FoFL}_{\mathrm{o}}$, OFL, and other applicable measures (if any) relevant to determining whether the stock is overfished or if overfishing is occurring: See table below. No vessels participated in the 2016 directed fishery and no bycatch was observed in crab fisheries in 2016; therefore total catch in 2016 was zero. Although 0.24 t of fishery mortality occurred during groundfish fisheries in 2016, this level of fishery mortality does not exceed the 2016 OFL. As such, overfishing did not occur in 2016. Values for the 2018 OFL and ABC are the author's recommendations.

Management Performance Table (values in t)

| Calendar <br> Year | MSST | Biomass <br> (MMB) | GHL $^{\text {a }}$ | Retained <br> Catch | Total <br> Catch $^{\text {b }}$ | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2013 | N/A | N/A | 68 | Conf. $^{\text {c }}$ | Conf. $^{\text {c }}$ | 91 | 82 |
| 2014 | N/A | N/A | 68 | Conf. $^{\text {c }}$ | Conf. $^{\text {c }}$ | 91 | 82 |
| 2015 | N/A | N/A | 59 | 0 | 1.92 | 91 | 68 |
| 2016 | N/A | N/A | 59 | 0 | 0.24 | 91 | 68 |
| 2017 | N/A | N/A | 59 |  |  | 93 | 70 |
| 2018 | N/A | N/A |  |  |  | 93 | 70 |

a. Guideline harvest level, established in lb and converted to t .
b. Total retained catch plus estimated bycatch mortality of discarded catch during crab and groundfish fisheries. Total reratined catch is not listed for 2013 and 2014 because the directed fishery is confidential under Sec. 16.05.815(SOA statute).
c. Confidential under Sec. 16.05.815 (SOA statute). GHL not attained.

## Management Performance Table (values in millions of lb)

| Calendar <br> Year | MSST | Biomass <br> (MMB) | GHL $^{\mathbf{a}}$ | Retained <br> Catch | Total <br> Catch $^{\text {b }}$ | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2013 | N/A | N/A | 150,000 | Conf. $^{\text {c }}$ | Conf. $^{\text {c }}$ | 0.20 | 0.18 |
| 2014 | N/A | N/A | 150,000 | Conf. $^{\text {c }}$ | Conf. $^{\text {c }}$ | 0.20 | 0.18 |
| 2015 | N/A | N/A | 130,000 | 0 | 0.004 | 0.20 | 0.15 |
| 2016 | N/A | N/A | 130,000 | 0 | $<0.001$ | 0.20 | 0.15 |
| 2017 | N/A | N/A | 130,000 |  |  | 0.20 | 0.15 |
| 2018 | N/A | N/A |  |  |  | 0.20 | 0.15 |

4. Specification of the retained-catch portion of the total-catch OFL:
a. Equation for recommended retained-portion of total-catch OFL.

Retained-catch portion = average retained catch during 1993-1998 (Table 5).
$=79 \mathrm{t}$.

Note that a retained catch of 79 t would exceed the author's recommended ABC for 2018 (70 t); see G.4, below.
5. Recommended Fofl, OFL total catch and the retained portion for the coming year:

See sections $\boldsymbol{F} .3$ and $\boldsymbol{F} .4$, above; no FofL is recommended for a Tier 5 stock.

## G. Calculation of ABC

1. PDF of OFL. A bootstrap estimates of the sampling distribution (assuming no error in estimation of discarded catch) of the status quo Alternative 1 OFL is shown in Figure 2 (1,000 samples drawn with replacement independently from each of the four columns of values in Table 5 to calculate $\mathrm{R}_{2001-2010}, \mathrm{RET}_{1993-1998}, \mathrm{BM}_{\mathrm{NC}, 1994-1998,} \mathrm{BM}_{\mathrm{GF}, 92 / 93-98 / 99}$, and $\mathrm{OFL}_{2016}$ ). The mean and CV computed from the 1,000 replicates are 92 t and 0.25 , respectively. Note that generated sampling distribution and computed standard deviation are meaningful as measures in the uncertainty of the OFL only if assumptions on the choice of years used to compute the Tier 5 OFL are true (see Sections E. 2 and E.4.f).

## 2. List of variables related to scientific uncertainty.

- Bycatch mortality rate in each fishery that discarded catch occurs. Note that for Tier 5 stocks, an increase in an assumed bycatch mortality rate will increase the OFL (and hence the ABC ), but has no effect on the retained-catch portion of the OFL or the retained-catch portion of the $A B C$.
- Estimated discarded catch and bycatch mortality for each fishery that discarded catch occurred in during 1993-1998.
- The time period to compute the average catch under the assumption of representing "a time period determined to be representative of the production potential of the stock."
- Stock size in 2018 is unknown.

3. List of additional uncertainties for alternative sigma-b. Not applicable to this Tier 5 assessment.
4. Author recommended ABC. $25 \%$ buffer on OFL; i.e., $\mathrm{ABC}=(1-0.25) \cdot(93 \mathrm{t})=70 \mathrm{t}$
(153,395 lb).

## H. Rebuilding Analyses

Not applicable; this stock has not been declared overfished.

## I. Data Gaps and Research Priorities

Data from the 2008-2012 biennial NMFS-AFSC eastern Bering Sea upper continental slope trawl surveys have been examined for their utility in determining overfishing levels and stock status by Gaeuman (2103a, 2013b) and Pengilly and Daly (2017). Cancellation of the survey that was scheduled for 2014 raised uncertainties on the prospects for obtaining fishery-independent survey data on this stock in the future; however, a slope survey was conducted in summer 2016. Those data are included in an updated discussion paper presented to the CPT.

## List of Tables.

Table 1a: Commercial fishery history for the Pribilof District golden king crab fishery, 1981/82 through 2016: number of vessels, guideline harvest level (GHL; established in lb, converted to $\mathbf{t}$ ), weight of retained catch (Harvest; $\mathbf{t}$ ), number of retained crab, pot lifts, fishery catch per unit effort (CPUE; retained crab per pot lift), and average weight ( $\mathbf{k g}$ ) of landed crab.

Table 1b: Commercial fishery history for the Pribilof District golden king crab fishery, 1981/82 through 2016: number of vessels, guideline harvest level (GHL; lb), weight of retained catch (Harvest; lb), number of retained crab, pot lifts, fishery catch per unit effort (CPUE; retained crab per pot lift), and average weight (lb) of landed crab.

Table 2: Weight $(\mathbf{t})$ of retained catch and estimated discarded catch of Pribilof golden king crab during crab fisheries, 1993-2016, with total fishery mortality ( $\mathbf{t}$ ) estimated by applying a bycatch mortality rate of 0.2 to the discarded catch in the directed fishery and a bycatch mortality rate of 0.5 to the discarded catch in the non-directed fisheries.

Table 3: Estimated annual weight (t) of discarded catch of Pribilof golden king crab (all sizes, males and females) during federal groundfish fisheries by gear type (fixed or trawl), 1991/922016, with total bycatch mortality (t) estimated by assuming bycatch mortality rate $=0.5$ for fixed-gear fisheries, and bycatch mortality rate $=0.8$ for trawl fisheries. 1991/92 to 2008/09 is listed bt crab fishing year, whereas 2009-2016 is listed by calendar year.

Table 4: Retained-catch weights (t) and estimates of discarded catch weights (t) of Pribilof Islands golden king crab available for a Tier 5 assessment; shaded, bold values are used in computation of the recommended (status quo Alternative 1) Tier 5 OFL.

Table 5: Data for calculation of $\operatorname{RET}_{1993-1998}(\mathbf{t})$ and estimates used in calculation of $\mathrm{R}_{\text {2001-2010 }}$ (ratio, t:t), $\mathrm{BM}_{\mathrm{NC}, 1994-1998}(\mathbf{t})$, and $\mathrm{BM}_{\mathrm{GF}, 92 / 93-98 / 99}(\mathbf{t})$ for calculation of the recommended (status quo Alternative 1) Pribilof Islands golden king crab Tier 52018 OFL (t); values under RET $_{1993-}$ 1998 are from Table 1, values under $\mathrm{R}_{2001-2010}$ were computed from the retained catch data and the directed fishery discarded catch estimates in Table 2 (assumed bycatch mortality rate $=0.2$ ), values under $\mathrm{BM}_{\mathrm{NC}, 1994-1998}$ were computed from the non-directed crab fishery discarded catch estimates in Table 2 (assumed bycatch mortality rate $=0.5$ ) and values under $\mathrm{BM}_{\mathrm{GF}, 92 / 93-98 / 99}$ are from Table 3.

## Table of Figures.

Figure 1: King crab Registration Area Q (Bering Sea), showing borders of the Pribilof District (from Figure 2-4 in Leon et al. 2017).

Figure 2: Bootstrapped estimates of the sampling distribution of the 2018 Alternative 1 Tier 5 OFL (total catch, t ) for the Pribilof Islands golden king crab stock; histogram on left, quantile plot on right.

## List of Appendices.

Appendix A1: EBS slope survey data on Pribilof Islands golden king crab and draft Pribilof Island golden king crab stock structure template (from Pengilly and Daly May 2017 report to Crab Plan Team).

Table 1a. Commercial fishery history for the Pribilof District golden king crab fishery, 1981/82 through 2016: number of vessels, guideline harvest level (GHL; established in lb, converted to $\mathbf{t}$ ), weight of retained catch (Harvest; $\mathbf{t}$ ), number of retained crab, pot lifts, fishery catch per unit effort (CPUE; retained crab per pot lift), and average weight (kg) of landed crab.

# Updated discussion paper for May 2017 Crab Plan Team meeting: Random effects approach to modeling NMFS EBS slope survey area-swept biomass estimates for Pribilof Islands golden king crab. 

Douglas Pengilly and Benjamin Daly<br>Alaska Department of Fish and Game, Kodiak, AK<br>Division of Commercial Fisheries<br>351 Research Ct.<br>Kodiak, AK 99615, USA<br>Phone: (907) 486-1865<br>Email: ben.daly@alaska.gov

## Introduction.

The Pribilof Islands golden king crab stock has been defined by the geographic borders of the Pribilof District (Figure 1) and has been managed as a Tier 5 stock (i.e., no reliable estimates of biomass and only historical catch data available) for determination of federal overfishing limits and annual catch limits (Pengilly 2014). Since 2011, the Council's Crab Plan Team (CPT) and the Scientific and Statistical Committee (SSC) have expressed interest in utilizing data collected during NMFS eastern Bering Sea (EBS) upper continental slope surveys (Hoff 2013) to establish an annual overfishing limit (OFL) and acceptable biological catch (ABC) on the basis of biomass estimates as an alternative to the standard Tier 5 historical-catch approach (see: reports of the June 2011, June 2012, June 2013, and October 2013 SSC meetings; reports of the May 2013 and September 2013 CPT meetings). Reviews of the EBS slope survey relative to the data collected on golden king crab, summaries of those data, and area-swept biomass estimates (Pengilly 2012, Gaeuman 2013a, 2013b), a Tier 4 approach to establishing OFL and ABC (Gaeuman 2013b), and "modified Tier 5" approach to establishing OFL and ABC (Gaeuman 2013a) have been presented to the CPT and SSC. Cancellation of the EBS biennial slope survey scheduled for 2014 precluded application of Gaeuman's (2013a) approach to establishment of OFL and ABC (see: report of the May 2015 CPT meeting; report of the June 2015 SSC meeting); however, the completion of the 2016 slope survey allows opportunity to revisit this approach.

In May 2015 the CPT recommended that, "a preliminary Tier 4 assessment be brought to the September 2015 meeting using available slope survey data and applying a Kalman filter approach (e.g., the program developed by Jim Ianelli for groundfish stock assessments)" (report of May 2015 CPT meeting). In June 2015, the SSC supported "the CPT recommendation that a preliminary Tier 4 assessment be brought to the September 2015 meeting, using existing slope data and applying a Kalman filter approach" (report of the June 2015 SSC meeting). The SSC also requested that the assessment include "a discussion ... of what stock delineation was chosen (what slope data were used) and the reason for that delineation," and that "a Stock Structure Template be completed for PI GKC" (report of the June 2015 SSC meeting). In September 2016 the CPT "recommends the random effects model be re-evaluated after results from the 2016
slope survey are available." The SSC confirmed that request:"The SSC concurs with the CPT recommendation" ["that the random effects model be re-evaluated after results from the 2016 slope survey are available"].

This report provides: results of applying the program developed for groundfish stock assessments to the slope survey area-swept biomass estimates of golden king crab; a discussion of the stock delineation chosen (what slope data were used and why); and a Stock Structure Template for Pribilof Islands golden king crab (Appendix C) that was prepared with the guidance of Spencer et al. (2010).

This report does not provide a Tier 4 assessment, however (i.e., no OFLs or ABCs are computed from the results of this exercise). Prior to computation of an OFL or ABC, the author would like to review the biomass estimates with the CPT so that the CPT can evaluate the results relative to the Tier 4 and Tier 5 criteria (i.e., Do the biomass estimates meet the "reliability" criterion for removing the stock from Tier 5? Do the results meet the Tier 4 criterion of having sufficient information for simulation modeling that captures the essential population dynamics of the stock?). Additionally, the term "Tier 4 assessment" in application to this stock since 2013 has lost its clarity, making it unclear if the requested assessment was to be made according to Tier 4 as defined in the FMP, according to the "modified Tier 5" approach of Gaeuman (2013a,b), or according to some modification to a Tier 4 assessment. Dependent on the evaluation of results and after clarification of the assessment approach, the computations of OFL and ABC can be performed with the results presented here.

## The NMFS EBS slope survey.

Only data from NMFS EBS slope trawl surveys performed in 2002 and later are used here. Although a pilot slope survey was also performed in 2000 and triennial surveys using a variety of nets, methods, vessels, and sampling locations were performed during 1979-1991, authors noted that, "Comparisons between the post-2000 surveys and those conducted from 1979-1991 remain confounded due to differences in sampling gear, survey design, sampling methodology, and species identification" (Hoff and Britt 2011). Starting in 2002, the slope survey was nominally a biennial survey, but no survey was performed in 2006 or 2014. Details on the methods and survey gear used in the 2002, 2004, 2008, 2010, 2012, and 2016 NMFS EBS slope surveys are provided in Hoff and Britt $(2003,2005,2009,2011)$ and $\operatorname{Hoff}(2013,2016)$, respectively. Those methods and the applicability of the slope survey data to golden king crab abundance and biomass estimation have also been summarized by Pengilly (2012) and Gaeuman (2013a,b).

Briefly, the survey samples from an area of $32,723 \mathrm{~km}^{2}$ in the $200-1,200 \mathrm{~m}$ depth zone. The surveyed area is divided into six subareas (Figure 2). Each subarea is divided into strata defined by 200 m depth zones and tows are performed at randomly-selected locations within each stratum, with target sampling density within strata proportional to the area in each subarea and stratum. Number of stations towed per survey ranged from 156 in 2002 to 231 in 2004; mean sampling density within strata ranged from approximately one tow per $162 \mathrm{~km}^{2}$ in 2004 to approximately one tow per $255 \mathrm{~km}^{2}$ in 2002. With regard to survey catchability of golden king crab by size and sex, the survey uses a Poly Nor'eastern high-opening bottom trawl equipped with mud-sweeper roller gear. ASFC scientists conveyed their opinion to the CPT during the May meeting that, with respect to golden king crab, "... the catchability of the slope net is less
than 1.0 and probably considerably lower than the shelf net due to the differences in the foot rope and surveyed habitat" (report of the May 2013 CPT meeting).

## Methods.

Data available by survey. Data on golden king crab that are available from the 2002, 2004, 2006, 2008, 20010, 2012 and 2016 NMFS EBS slope surveys are summarized in Table 1.

Although the CPT and SSC both suggested that NMFS would "provide the author with slope survey CPUE data based on State statistical areas or other stratification instead of the entire slope survey area because the entire survey extends beyond the Pribilof management area" (reports of the May 2015 CPT meeting and June 2015 SSC meeting), the author did not find it necessary or useful for this exercise to receive the data stratified by State statistical area or by any other stratification besides that defined by the survey design.

Data summarization: area-swept biomass estimates. Area-swept estimates of total (male and female, all sizes) biomass and variances of estimates within strata within survey subarea for 2002, 2004, 2008, 2010, and 2012 were obtained directly from the tables presented in Hoff and Britt (2003; 2005; 2009; 2011) and Hoff (2013). For area-swept biomass estimation of mature males and legal males from the 2008, 2010, 2012, and 2016 survey data, 107 mm CL was used as a proxy for size at maturity (Somerton and Otto 1986) and 124 mm CL was used as a proxy for the 5.5 in carapace width (including spines) legal size (NPFMC 2007); weight of males was estimated from the CL measured during the survey by weight $(\mathrm{g})=(0.0002988) \times(\mathrm{CL})^{3.135}$ (NPFMC 2007). An area-swept estimate of biomass and of the variance of the biomass estimate was computed for each stratum within a survey subarea and summed over strata within the subarea to obtain area-swept estimates of biomass within a subarea and of the variance of that biomass estimate; estimates of the biomass and associated variances within subareas were summed over subareas to obtain biomass estimates in aggregates of subareas and of the variances of those estimates.

Model estimates of biomass and projections to 2018. ${ }^{1}$ The program "re.exe" was used to estimate biomass from the area-swept estimates in surveyed years and to project biomass estimates for unsurveyed years into 2018 via a state-space random walk plus noise model. The state-space random walk plus noise is formulated as a random effect model. The random effects model considers the process errors as "random effects" (i.e., drawn from an underlying distribution) and integrated out of the likelihood. The method was developed by the NPFMC groundfish plan team's survey averaging working group as a smoothing technique similar to the Kalman Filter, but which provides more flexibility with non-linear processes and non-normal error structures.

Stock delineation chosen (what slope data were used). The author followed the guidance provided by the SSC in June 2013 (report of the June 2013 SSC meeting):

[^9]
#### Abstract

"Because the stock structure is unknown, the SSC recommends that the authors examine maps of catch-per-unit-effort by survey year to identify natural breaks in the spatial distribution of golden king crab along the slope. If no obvious breaks exist, the SSC recommends that the authors bring forward biomass estimates for the Pribilof canyon region and for the slope as a whole. However, we note that the Pribilof Canyon stations do not encompass the historical catches, which occurred inside and to the north of Pribilof Canyon. Therefore, the authors should consider a biomass estimate for an area that encompasses the majority of historical catches."

Figures 3-8 show CPUE ( $\mathrm{kg} \mathrm{km}^{-2}$ ) of golden king crab (males and females, all sizes) by tow and survey subarea during the 2002, 2004, 2008, 2010, 2012, and 2016 NMFS EBS slope surveys relative to the boundaries of the Pribilof District. Highest survey CPUE occurs at tows within survey subareas 2-4 (particularly in subarea 2; i.e., Pribilof Canyon). Tows performed in the portion of subarea 5 that lie within the Pribilof District have produced little or no catch of golden king crab, indicating a gap in golden king crab distribution between subarea 4 and the portion of the surveyed area north of the Pribilof District boundary (i.e., the portion of subarea 5 that is north of the Pribilof District boundary and all of subarea 6). Tows performed in subarea 1 that are within the Pribilof District have produced little or no catch of golden king crab, indicating a gap in distribution between Pribilof Canyon and the area east of the Pribilof District within subarea 1. It appears that the areas of subareas 1 and 5 that lie within the Pribilof District support limited densities of golden king crab. Subarea 3 appears to support only low-to-moderate densities of golden king crab relative to subarea 4 and - especially - subarea 2; tows with catch of golden king crab occurred sporadically within subarea 3, with highest densities occurring near the border of subarea 4 in 2010 and 2012 and near the border of subarea 2 in 2002.

Figure 9 shows the distribution of all 6,104 pot lifts sampled by observers with locations recorded during 1992-2014 Bering Sea golden king crab fisheries (including the Saint Matthew section of the Northern District, which is north of the Pribilof District) relative to the borders of the Pribilof District and of the survey subareas. Only one of those locations is within the portion of subarea 5 that is within the Pribilof District, none are within the portion of subarea 1 that is within the Pribilof District, and none are within subarea 3.

Figure 10 shows the 26 statistical areas with reported catch during the 1985-2014 Pribilof District golden king crab fisheries relative to the borders of the Pribilof District and of the survey subareas: one (accounting for $0.7 \%$ of the 1985-2014 total catch) lies largely in subarea 4, but extends into subarea 5 ; four ( $2.9 \%$ of the total catch) include portions of subarea 4 ; six ( $1.5 \%$ of total catch) include portions of subarea 3; one ( $8.9 \%$ of total catch) includes portions of subareas 3 and 2 ; four ( $83.9 \%$ of total catch) are in or extend into subarea 2 ; one ( $0.7 \%$ of total catch) includes portions of subareas 2 and 1 ; one ( $<0.1 \%$ of total catch) is largely within subarea 1 ; and eight ( $1.4 \%$ of total catch) are outside of the survey area (some of those may be errors in recording of statistical area).

This review of survey distribution and fishery catch and effort distribution shows that golden king crab in the Bering Sea and the fishery for golden king crab in the Bering Sea are concentrated in the Pribilof Canyon area (survey subarea 2). Nonetheless, golden king crab do
occur more sporadically and at lower densities in survey subareas 3 and 4 and there has been some limited catch and effort during Pribilof District fisheries within survey subareas 3 and 4. Portions of survey subareas 1 and 5 that lie within the Pribilof District appear to be largely devoid of golden king crab, have received little or no fishery effort during the Pribilof District fishy, and thus have produced little or no catch. The golden king crab that occur in survey subarea 6 are exploited by the Saint Matthew section fishery when it is prosecuted. Accordingly, the following analyses to estimate trends in the Pribilof District stock were performed using survey data from only survey subareas 2,3 , and 4 . Data summaries and analyses were also performed using data only from survey Subarea 2 due to the high concentration of fishery effort and fishery catch in Pribilof Canyon and the high CPUE of golden king crab within Pribilof Canyon during the slope surveys,.

## Results.

Size frequency distributions of golden king crab captured within subareas 2, 3, and 4 during the 2008, 2010, 2012, 2016 NMFS EBS slope surveys are shown in Figures 11-14.

Area-swept biomass estimates by survey subarea, for the total surveyed area (pooled subareas 1 6 ), and for pooled subareas 2-4 for 2002, 2004, 2008, 2010, 2012 and 2016 are in Table 2.

Estimates and projections through 2018 of total, mature male, and legal male biomass in survey subareas 2-4 and survey subarea 2 from the state-space random walk plus noise model are plotted in Figures 15 and 16, respectively. More detailed results produced by re.exe are provided in Appendices A and B.

Locations of all pots sampled by observers during Bering Sea golden king crab fisheries ( $n=6,104$ ), 1992-2014; pots north of the Pribilof District northern boundary were fished during the Northern District - Saint Matthew Island Section fishery; squares are $1^{\circ}$ longitude $\times 30^{\prime}$ latitude State statistical areas.

Figure 10. Statistical areas with reported catch during the 1985-2014 Pribilof District golden king crab fisheries: filled red squares denote statistical areas with reported catch; size of overlain white circles are proportional to the percentage of the total 1985-2014 catch reported from statistical area (biggest circle $=68 \%$ of total); squares are $1^{\circ}$ longitude x 30' latitude State statistical areas.

Figure 11. Size distribution of measured golden king crab during the 2008 NMFS EBS slope survey in survey Subareas 2, 3, and 4, by survey subarea.

Figure 12. Size distribution of measured golden king crab during the 2010 NMFS EBS slope survey in survey Subareas 2, 3, and 4, by survey subarea.

■ Male Female

■ Male Female

Figure 13. Size distribution of measured golden king crab during the 2012 NMFS EBS slope survey in survey Subareas 2, 3, and 4, by survey subarea.

Figure 14. Size distribution of measured golden king crab during the 2016 NMFS EBS slope survey in survey Subareas 2, 3, and 4, by survey subarea.

Figure 15. Plots of estimated and projected (into 2018) biomass of total, mature male, and legal male golden king crab in NMFS slope survey Subareas 2-4 with $90 \%$ confidence intervals and survey area-swept estimates; red bars are survey estimates $\pm 2$ standard errors.

Figure 16. Plots of estimated and projected (into 2018) biomass of total, mature male, and legal male golden king crab in NMFS slope survey Subarea 2 with $90 \%$ confidence intervals and survey area-swept estimates; red bars are survey estimates $\pm 2$ standard errors.

Appendix A1. Input file (re.dat) for total golden king crab biomass in NMFS EBS slope survey Subareas 2-4 and results file (rwout.rep) produced by re.exe.

| Factor and criterion | Justification |
| :---: | :---: |
| Harvest and trends |  |
| Fishing mortality <br> (5-year average percent of $\mathrm{F}_{\text {abc }}$ or $\mathrm{F}_{\text {ofl }}$ ) | F, $\mathrm{F}_{\mathrm{ABC}}$, and Fofl are not estimated for Tier 5 stock. Total catch annual catch is confidential, but has been below the OFLs and ABCs established for season. |
| Spatial concentration of fishery relative to abundance (Fishing is focused in areas << management areas) | Fishery effort and catch is concentrated in Pribilof Canyon, a very small area of the Pribilof District, but also an area of concentrated golden king crab density (see EBS slope survey data). |
| Population trends (Different areas show different trend directions) | Uncertain. Standardized trawl surveys in the Pribilof District have only been performed in 2002, 2004, 2008, 2010, 2012, and 2016. Total biomass estimates generally increased from 2002 through 2012; with no substantial increase in 2016. |
| Barriers and phenotypic characters |  |
| Generation time (e.g., >10 years) | Unknown, but likely >10 years. |
| Physical limitations (Clear physical inhibitors to movement) | Species occurs primarily in the 200-1000 m depth zone. No known physical barriers exist in the Pribilof District, although survey and fishery data suggest low densities in the 200-1000 m depth zone of the EBS slope between Pribilof Canyon and Zhemchug Canyon. |
| Growth differences <br> (Significantly different LAA, WAA, or LW parameters) | No data for estimating size at age. Spatial differences in lengthweight relationship within Pribilof District have not been investigated. Within the Bering Sea males at higher latitudes have been estimated to be heavier than equal-sized males at lower latitudes. |
| Age/size-structure (Significantly different size/age compositions) | Age structure data is lacking. Spatial trends within Pribilof District in size structure have not been investigated, but trend of latitudinal decrease in mean size may exist over the Bering Sea due to latitudinal decrease in size at maturity. |
| Spawning time differences (Significantly different mean time of spawning) | Species is known to exhibit an asynchronous reproductive cycle lacking distinct seasonal variation; mean spawning time within Pribilof District has not been estimated. |

| Factor and criterion | Justification |
| :--- | :--- |
| Maturity-at-age/length differences <br> (Significantly different mean maturity- <br> at-age/ length) | No data for estimating maturity at age. Spatial differences in size at <br> maturity within Pribilof District have not been investigated. Within <br> Bering Sea, estimates of size at maturity decrease south-to-north. |
| Morphometrics (Field identifiable <br> characters) | Spatial trends within Pribilof District in morphometrics have not <br> been investigated. Latitudinal trends in male morphometrics (chela <br> size at length) may exist over the Bering Sea that are related to <br> latitudinal trends in size at maturity. |
| Meristics (Minimally overlapping <br> differences in counts) | N/A. |
|  |  |
| Spawning site fidelity (Spawning <br> individuals occur in same location <br> consistently) | Not likely: ovigerous females tend to occur in the shallower depth <br> zones at sites throughout the Pribilof District within the species <br> depth distribution. |
| Mark-recapture data (Tagging data may <br> show limited movement) | Mark-recapture data not available. |
| Natural tags (Acquired tags may show <br> movement smaller than management <br> areas) | Unknown. |
|  |  |
| lsolation by distance <br> (Significant regression) |  |
| Dispersal distance (<<Management <br> areas) | Unknown. |
| Pairwise genetic differences (Significant <br> differences between geographically <br> distinct collections) | Unknown. |

# 10. Assessment of Western Aleutian Islands Red King Crab (WAIRKC) 

## [2017]

Benjamin Daly, ADF\&G, Kodiak
Alaska Department of Fish and Game
Division of Commercial Fisheries
[NOTE: In accordance with the approved schedule, no assessment was conducted for this stock this year, however, a full stock assessment will be conducted in 2020. Until then, the values generated from the previous stock assessment (below) will be rolled over for 2018 specifications]

## Summary of Results

## Executive Summary

## 1. Stock:

Western Aleutian Islands (the Aleutian Islands, west of $171^{\circ} \mathrm{W}$ longitude) red king crab, Paralithodes camtschaticus

There are two districts for State management of commercial red king crab fisheries in waters of the Aleutian Islands west of $171^{\circ} \mathrm{W}$ longitude: the Adak District for waters east of $179^{\circ} \mathrm{W}$ longitude and the Petrel District for waters west of $179^{\circ} \mathrm{W}$ longitude. Although this stock has been referred to colloquially as the "Adak" stock, this report will refer to the stock as the "Western Aleutian Islands (WAI) red king crab" stock to avoid confusion with the Adak District.

## 2. Catches:

The domestic fishery has been prosecuted since 1960/61 and was opened every year through the 1995/96 crab fishing year. Peak retained catch occurred in 1964/65 at 9,613 t (21,193,000 lb). During the early years of the fishery through the late 1970s, most or all of the retained catch was harvested in the area between $172^{\circ} \mathrm{W}$ longitude and $179^{\circ} 15^{\prime} \mathrm{W}$ longitude. As the annual retained catch decreased into the mid-1970s and the early-1980s, the area west of $179^{\circ} 15^{\prime} \mathrm{W}$ longitude began to account for a larger portion of the retained catch. Retained catch during the 10 -year period 1985/86-1994/95 averaged $428 \mathrm{t}(942,940 \mathrm{lb})$, but the retained catch in 1995/96 was only $18 \mathrm{t}(38,941 \mathrm{lb})$. The fishery has been opened only occasionally during 1996/97 to present. There was an exploratory fishery with a low guideline harvest level (GHL) in 1998/99, three commissioner's permit fisheries in limited areas during 2000/01-2002/03 to allow for ADF\&GIndustry surveys, and two commercial fisheries with a GHL of $227 \mathrm{t}(500,000 \mathrm{lb})$ in 2002/03 and 2003/04. Most of the retained catch since 1990/91 was harvested in the Petrel Bank area (between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude); in 2002/03 and 2003/04 the commercial fishery was opened only in the Petrel Bank area. Retained catch in the last two years with commercial fishing was $229 \mathrm{t}(505,642 \mathrm{lb})$ in 2002/03 and $217 \mathrm{t}(479,113 \mathrm{lb})$ in 2003/04. The fishery has been closed during 2004/05-2016/17. Discarded (non-retained) catch of red king crab occurs in the directed red king crab fishery (when prosecuted), in the Aleutian Islands golden king crab fishery, and in groundfish fisheries. Estimated annual weight of bycatch mortality due
to crab fisheries during 1995/96-2016/17 averaged 1 t (1,902 lb). Estimated annual weight of bycatch mortality due to groundfish fisheries during 1993/94-2016/17 averaged $7 \mathrm{t}(15,710 \mathrm{lb})$. Estimated weight of annual total fishery mortality during 1995/96-2016/17 averaged 34 t $(74,890 \mathrm{lb})$; the average annual retained catch during that period was $26 \mathrm{t}(57,278 \mathrm{lb})$. A cooperative red king crab survey was performed by the Aleutian Islands King Crab Foundation (an industry group) and ADF\&G in the Petrel Bank area in November 2016 (Hilsinger and Siddon 2016b), which resulted in an estimated bycatch mortality of $0.03 \mathrm{t}(59 \mathrm{lb})$. Estimated total fishery mortality in $2016 / 17$ resulted from groundfish fisheries ( $0.13 \mathrm{t} ; 294 \mathrm{lb}$ ), the Aleutian Islands golden king crab fishery ( $0.05 \mathrm{t} ; 100 \mathrm{lb}$ ), and the cooperative survey ( $0.03 \mathrm{t} ; 59 \mathrm{lb}$ ).
3. Stock biomass:

Estimates of past or present stock biomass are not available for this Tier 5 assessment.

## 4. Recruitment:

Estimates of recruitment trends and current levels relative to virgin or historic levels are not available for this Tier 5 assessment.

## 5. Management performance:

Overfishing did not occur during 2016/17 because the estimated total catch ( $0.2 \mathrm{t} ; 454 \mathrm{lb}$ ) did not exceed the Tier 5 OFL established for 2016/17 ( 56 t ; 123,867 lb). Additionally, the 2016/17 estimated total catch did not exceed the ABC established for 2016/17 (34 t; 74,320 lb). No determination has yet been made for a fishery opening or harvest level, if opened, for 2017/18. The OFL and ABC values for 2017/18 in the tables below are the author's status quo, Alternative 1 recommended values.

Management Performance Table (values in t)

| Fishing <br> Year | MSST | Biomass <br> (MMB) | TAC $^{\text {a }}$ | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2012 / 13$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2013 / 14$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2014 / 15$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2015 / 16$ | N/A | N/A | Closed | 0 | 1.3 | 56 | 34 |
| $2016 / 17$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2017 / 18$ | N/A | N/A |  |  |  | 56 | 14 |

a. Pre-season harvest levels are established as total allowable catch for the rationalized fishery west of $179^{\circ} \mathrm{W}$ longitude and as a guideline harvest level for the non-rationalized fishery east of $179^{\circ} \mathrm{W}$ longitude.

Management Performance Table (values in lb)

| Fishing <br> Year | MSST | Biomass <br> (MMB) | TAC $^{\mathbf{a}}$ | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2012 / 13$ | N/A | N/A | Closed | 0 | 624 | 123,867 | 74,320 |
| $2013 / 14$ | N/A | N/A | Closed | 0 | 732 | 123,867 | 74,320 |
| $2014 / 15$ | N/A | N/A | Closed | 0 | 474 | 123,867 | 74,320 |
| $2015 / 16$ | N/A | N/A | Closed | 0 | 2,964 | 123,867 | 74,320 |
| $2016 / 17$ | N/A | N/A | Closed | 0 | 454 | 123,867 | 74,320 |
| $2017 / 18$ | N/A | N/A |  |  |  | 123,867 | 30,967 |

a. Pre-season harvest levels are established as total allowable catch for the rationalized fishery west of $179^{\circ} \mathrm{W}$ longitude and as a guideline harvest level for the non-rationalized fishery east of $179^{\circ} \mathrm{W}$ longitude.
6. Basis for the OFL and ABC: See table, below; values for $2017 / 18$ are the author's recommended values.

| Year | Tier | Years to define <br> Average catch (OFL) | Natural <br> Mortality | Buffer |
| :---: | :---: | :---: | :---: | :---: |
| $2012 / 13$ | 5 | $1995 / 96-2007 / 08^{\mathrm{a}}$ | $0.18^{\mathrm{b}}$ | $40 \%$ |
| $2013 / 14$ | 5 | $1995 / 96-2007 / 08^{\mathrm{a}}$ | $0.18^{\mathrm{b}}$ | $40 \%$ |
| $2014 / 15$ | 5 | $1995 / 96-2007 / 08^{\mathrm{a}}$ | $0.18^{\mathrm{b}}$ | $40 \%$ |
| $2015 / 16$ | 5 | $1995 / 96-2007 / 08^{\mathrm{a}}$ | $0.18^{\mathrm{b}}$ | $40 \%$ |
| $2016 / 17$ | 5 | $1995 / 96-2007 / 08^{\mathrm{a}}$ | $0.18^{\mathrm{b}}$ | $40 \%$ |
| $2017 / 18$ | 5 | $1995 / 96-2007 / 08^{\mathrm{a}}$ | $0.18^{\mathrm{b}}$ | $75 \%$ |

a. OFL is for total catch and was determined by the average of the total catch for these years.
b. Assumed value for FMP king crab in NPFMC (2007); does not enter into OFL estimation for Tier 5 stock.
7. PDF of the OFL: Sampling distribution of the recommended (status quo Alternative 1) Tier 5 OFL was estimated by bootstrapping (see section G.1). The standard deviation of the estimated sampling distribution of the recommended OFL is $56 \mathrm{t}(\mathrm{CV}=0.42)$. Note that generated sampling distribution and computed standard deviation are meaningful as measures in the uncertainty of the OFL only if assumptions on the choice of years used to compute the Tier 5 OFL are true (see Section E.4.f).
8. Basis for the ABC recommendation: The recommended ABC of 14 t is less than the ABC that was recommended by the SSC for 2012/13 - 2016/17. The recommended ABC is lowered because 1) the industry has not expressed interest in a small test fishery during 2017/18, and 2) because the stock is severely depressed as indicated by the 2016 Petrel survey (CPT minutes for May 2017).

At 14 t the ABC provides a $75 \%$ buffer on the OFL of 56 t ; i.e., (1.0-0.75). $56 \mathrm{t}=14 \mathrm{t}$.
9. A summary of the results of any rebuilding analyses: Not applicable; stock is not under a rebuilding plan.

## A. Summary of Major Changes

1. Changes to the management of the fishery: No changes have been made to management of the fishery (the fishery has remained closed) and no changes have been made to regulations pertaining to the fishery since those adopted by the Alaska Board of Fisheries in March 2014.
2. Changes to the input data:

- Data on retained catch, discarded catch, and estimates of bycatch mortality in crab and groundfish fisheries during 2016/17 have been added, but were not entered into the calculation of the recommended 2017/18 total-catch OFL.

3. Changes to the assessment methodology: None: the computation of OFL in this assessment follows the methodology recommended by the SSC in June 2010.
4. Changes to the assessment results, including projected biomass, TAC/GHL, total catch (including discard mortality in all fisheries and retained catch), and OFL: None: the computation of OFL in this assessment follows the methodology recommended by the SSC in June 2010 applied to the same data and estimates with the same assumptions that were used for estimating the 2010/11-2016/17 OFLs.

## B. Responses to SSC and CPT Comments

1. Responses to the most recent two sets of SSC and CPT comments on assessments in general:

- CPT, May 2016: None pertaining to a Tier 5 assessment.
- SSC, June 2016: None pertaining to a Tier 5 assessment.
- CPT, September 2016 (via September 2015 SAFE Introduction chapter): None pertaining to a Tier 5 assessment.
- SSC, October 2015: None pertaining to a Tier 5 assessment.

2. Responses to the most recent two sets of SSC and CPT comments specific to the assessment:

- CPT, May 2016: None.
- SSC, June 2015: "The industry expressed no desire to pursue a red king crab fishery in the Adak area at this time. However, the Petrel Bank region will be surveyed during September 2016."
- Response: The Petrel survey was conducted in November 2016 and showed very little RKC (ave CPUE=0.11).
- "The SSC also appreciates the addition of size frequency data in Appendices A1-A4. The SSC requests plotting these data to enable visualization of progression of size modes in next year's assessment. "
- Response: Done. See appendix A5.
- CPT, September 2016: None.
- SSC, October 2016: None.

## C. Introduction

1. Scientific name: Paralithodes camtschaticus, Tilesius, 1815

## 2. Description of general distribution:

The general distribution of red king crab is summarized by NMFS (2004):
Red king crab are widely distributed throughout the BSAI, GOA, Sea of Okhotsk, and along the Kamchatka shelf up to depths of 250 m . Red king crab are found from eastern Korea around the Pacific rim to northern British Columbia and as far north as Point Barrow (page 3-27).

Most red and blue king crab fisheries occur at depths from 50-200 m, but red king crab fisheries in the Aleutian Islands sometimes extend to 300 m .

Red king crab is native to waters of 300 m or less extending from eastern Korea, the northern coast of the Japan Sea, Hokkaido, the Sea of Okhotsk, through the eastern Kamchatkan Peninsula, the Aleutian Islands, the Bering Sea, the GOA, and the Pacific Coast of North America as far south as Alice Arm in British Columbia. They are not found north of the Kamchatkan Peninsula on the Asian Pacific Coast. In North America red king crab range includes commercial fisheries in Norton Sound and sparse populations extending through the Bering Straits as far east as Barrow on the northern coast of Alaska. Red king crab have been acclimated to Atlantic Ocean waters in Russia and northern Norway. In the Bering Sea, red king crab are found near the Pribilof Islands and east through Bristol Bay; but north of Bristol Bay ( 58 degrees 39 minutes) they are associated with the mainland of Alaska and do not extend to offshore islands such as St . Matthew or St. Laurence Islands.

Commercial fishing for WAI red king crab was opened only in the Petrel Bank area (i.e., between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude; Baechler and Cook 2014) during the most recent two years that the fishery was prosecuted (2002/03 and 2003/04). Fishery effort during those two years typically occurred at depths of $60-90$ fathoms ( $110-165 \mathrm{~m}$ ); average depth of pots fished in the Aleutian Islands area during 2002/03 was 68 fathoms ( 124 m ; Barnard and Burt 2004) and during 2003/04 was 82 fathoms ( 151 m ; Burt and Barnard 2005). Depth was recorded for 578 pots out of the 580 pot lifts sampled by observers during the 1996/97-2006/07 Aleutian Islands golden king crab fishery that contained 1 or more red king crab (ADF\&G observer database, Dutch Harbor, April 2008). Of those, the deepest recorded depth was 266 fathoms ( 486 m ) and $90 \%$ of pot lifts had recorded depths of 100-200 fathoms (183-366 m) ; no red king crab were present in any of the 6,465 pot lifts sampled during the 1996/97-2006/07 Aleutian Islands golden king crab fishery with depths >266 fathoms ( 486 m ).

In this chapter we will refer to the area west of $171^{\circ} \mathrm{W}$ longitude within the Aleutian Islands king crab Registration Area O as the "Western Aleutian Islands" (WAI). The Aleutian Islands king crab Registration Area O is described by Baechler and Cook (2014, page 7) as follows (see also Figure 1):

#### Abstract

"The Aleutian Islands king crab Registration Area O has as its eastern boundary the longitude of Scotch Cap Light ( $164^{\circ} 44^{\prime} \mathrm{W}$ longitude), its northern boundary a line from Cape Sarichef ( $54^{\circ} 36^{\prime} \mathrm{N}$ latitude) to $171^{\circ} \mathrm{W}$ longitude, north to $55^{\circ} 30^{\prime}$ N latitude, and as its western boundary the Maritime Boundary Agreement Line as that line is described in the text of and depicted in the annex to the Maritime Boundary Agreement between the United States and the Union of Soviet Socialist Republics signed in Washington, June 1, 1990. Area O encompasses both the waters of the Territorial Sea ( $0-3$ nautical miles) and waters of the Exclusive Economic Zone (3-200 nautical miles)."

From 1984/85 until the March 1996 Alaska Board of Fisheries meeting, the Aleutian Islands king crab Registration Area O as currently defined had been subdivided at $171^{\circ} \mathrm{W}$ longitude into the historic Adak Registration Area R and the Dutch Harbor Registration Area O. The geographic boundaries of the WAI red king crab stock are defined here by the boundaries of the historic Adak Registration Area R (i.e., the current Aleutian Islands king crab Registration Area O, west of $171^{\circ}$ W longitude). Note that in March 2014 the Alaska Board of Fisheries established two districts for management of commercial fisheries for red king crab in the waters of the Aleutian Islands west of $171^{\circ} \mathrm{W}$ longitude: 1) the Adak District, $171^{\circ}$ to $179^{\circ} \mathrm{W}$ longitude; and the Petrel District, west of $179^{\circ} \mathrm{W}$ longitude.

## 3. Evidence of stock structure:

Seeb and Smith (2005) analyzed microsatellite DNA variability in nearly 1,800 individual red king crab originating from the Sea of Okhotsk to Southeast Alaska, including a sample 75 specimens collected during 2002 from the vicinity of Adak Island in the Aleutian Islands (51 51' N latitude, $176^{\circ} 39^{\prime} \mathrm{W}$ longitude), to evaluate the degree to which the established geographic boundaries between stocks in the BSAI reflect genetic stock divisions. Seeb and Smith (2005) concluded that, "There is significant divergence of the Aleutian Islands population (Adak sample) and the Norton Sound population from the southeastern Bering Sea population (Bristol Bay, Port Moller, and Pribilof Islands samples)." Recent analysis of patterns of genetic diversity among red king crab stocks in the western north Pacific (Asia), eastern North Pacific, and Bering Sea by multiple techniques (SNPs, allozymes, and mtDNA) also showed that red king crab sampled near Adak Island had greater genetic similarity to stocks in Asia rather than other stocks in Alaskan waters including Bristol Bay and the Gulf of Alaska (reviewed in Grant et al. 2014).

To date, population genetic studies of red king crab within the WAI have only grouped samples from within this region as one site (i.e., Adak Island) (Grant et al. 2014). Given the complexity of currents throughout the WAI and that canyons deeper than the depth restrictions of red king crab ( $>1,000 \mathrm{~m}$ ) separate several islands, the possibility of fine scale genetic structuring exists, but remains uninvestigated. A summary of total retained catch by 1-degree longitude groupings during 1985/86-1995/96 (years for which state statistical area definitions allow for grouping by 1-degree longitude and for which catch distribution was not affected by area closures and openings; see Section C.5) shows that catch and, presumably, distribution of legal-sized male red king crab is not evenly distributed across the Aleutian Islands. Most catch during that period was from Petrel Bank, followed by the vicinity of Adak, Atka, and Amlia Islands (Figure 2). Note that the 1-degree longitude grouping of catch does not portray the spatial gaps in catch that are apparent upon a closer inspection of the 1985/86-1995/96 catch data by state statistical areas.

For example, no catch was reported during 1985/86-1995/96 from the two statistical areas (795102 and 795132) that include Amchitka Pass (Amchitka Pass lies between Petrel Bank and the Delarof Islands; see Figure 2).

McMullen and Yoshihara (1971) reported the following on male red king crab that were tagged in February 1970 on the Bering Sea and Pacific Ocean sides of Atka Island and recovered in the subsequent fishery:
"Fishermen landing tagged crabs were questioned carefully concerning the location of recapture. In no instance did crabs migrate through ocean passes between the Pacific Ocean and Bering Sea."

## 4. Description of life history characteristics relevant to stock assessments (e.g., special features of reproductive biology):

Red king crab eggs are fertilized externally and the clutch of fertilized eggs (embryos) are carried under the female's abdominal flap until hatching. Male king crab fertilize eggs by passing spermatophores from the fifth periopods to the gonopores and coxae of the female's third periopods; the eggs are fertilized during ovulation and attach to the female's pleopodal setae (Nyblade 1987, McMullen 1967). Females are generally mated within hours after molting (Powell and Nickerson 1965), but may mate up to 13 days after molting (McMullen 1969). Males must wait at least 10 days after completing a molt before mating (Powell et al. 1973), but, unlike females, do not need to molt prior to mating (Powell and Nickerson 1965).

Wallace et al. (1949, page 23) described the "egg laying frequency" of red king crab:
> "Egg laying normally takes place once a year and only rarely are mature females found to have missed an egg laying cycle. The eggs are laid in the spring immediately following shedding [i.e., molting] and mating and are incubated for a period of nearly a year. Hatching of the eggs does not occur until the following spring just prior to moulting [i.e., molting] season."

McMullen and Yoshihara (1971) reported that from 804 female red king crab (79-109-mm CL) collected during the 1969/70 commercial fishery in the western Aleutians, "Female king crab in the western Aleutians appeared to begin mating at 83 millimeters carapace length and virtually all females appeared to be mature at 102 millimeters length." Blau (1990) estimated size at maturity for WAI red king crab females as the estimated CL at which $50 \%$ of females are mature (SM50; as evidenced by presence of clutches of eggs or empty) according to a logistic regression: $89-\mathrm{mm}$ CL ( $\mathrm{SD}=2.6 \mathrm{~mm}$ ). Size at maturity has not been estimated for WAI male red king crab. However, because the estimated SM50 for WAI red king crab females is the same as that estimated for Bristol Bay red king crab females (Otto et al. 1990), the estimated maturity schedule used for Bristol Bay red king crab males (see SAFE chapter on Bristol Bay red king crab) could be applied to males in the WAI stock as a proxy.

Few data are available on the molting and mating period for red king crab specifically in the WAI. Among the red king crab captured by ADF\&G staff for tagging on the south side of Amlia Island ( $173^{\circ} \mathrm{W}$ longitude to $174^{\circ} \mathrm{W}$ longitude) in the first half of April 1971, males and females
were molting, females were hatching embryos, and mating was occurring (McMullen and Yoshihara 1971). The spring mating period for red king crab is known to last for several months, however. For example, although mating activity in the Kodiak area apparently peaks in April, mating pairs in the Kodiak area have been documented from January through May (Powell et al. 2002). Due to the timing of the commercial fishery within a year, little data on reproductive condition of WAI red king crab females have been collected by at-sea fishery observers that can be used for evaluating the mating period. Most recently, of the 3,211 mature females that were examined during the 2002/03 and 2003/04 red king crab fisheries in the Petrel Bank area, which were prosecuted in late October, only 10 were scored as "hatching" (ADF\&G observer database, Dutch Harbor, April 2008).

Data on mating pairs of red king crab collected from the Kodiak area during March-May of 1968 and 1969 showed that size of the females in the pairs increased from March to May, indicating that females tend to release their larvae and mate later in the mating season with increasing body size (Powell et al. 2002). Size of the males in those mating pairs did not increase with later sampling periods, but did show a decreasing trend in estimated time since last molt. In all the data on mating pairs collected from the Kodiak area during 1960-1984, the proportion of males that were estimated to have not recently molted prior to mating decreased monthly over the mating period (Powell et al. 2002). Those data also suggest that, for males, not molting early in the mating period provides the advantage of mating when primiparous and small, multiparous females tend to ovulate. Alternatively, males that do molt early in the mating period likely participate in mating later, and with larger females.

Current knowledge of red king crab reproductive biology, including male and female maturation, migration, mating dynamics, and potential effects of exploitation on reproductive potential, is summarized by Webb (2014).

## 5. Brief summary of management history:

A complete summary of the management history through 2011/12 is provided by Baechler and Cook (2014, pages 7-13). The domestic fishery for red king crab in the WAI began in 1960/61. Retained catch of red king crab in the Aleutians west of $172^{\circ} \mathrm{W}$ longitude averaged $5,259 \mathrm{t}$ $(11,595,068 \mathrm{lb})$ during $1960 / 61-1975 / 76$, with a peak retained catch of $9,613 \mathrm{t}(21,193,000 \mathrm{lb})$ in 1964/65 (Tables 1a and 1b, Figure 3). Guideline harvest levels (GHL; sometimes expressed as ranges, with an upper and lower GHL) for the fishery were established in most years since 1973/74. The fishery was closed in 1976/77 in the area west of $172^{\circ} \mathrm{W}$ longitude, but was reopened for each year during 1977/78-1995/96. Average retained catch during 1977/78$1995 / 96$ (for the area west of $172^{\circ} \mathrm{W}$ longitude prior to $1984 / 85$ and for the area west of $171^{\circ} \mathrm{W}$ longitude since $1984 / 85$ ) was $470 \mathrm{t}(1,036,659 \mathrm{lb})$; the peak retained catch during that period occurred in 1983/84 at $899 \mathrm{t}(1,981,579 \mathrm{lb})$. During the mid-to-late 1980s, significant portions of the catch during the WAI red king crab fishery occurred west of $179^{\circ} \mathrm{E}$ longitude or east of $179^{\circ}$ W longitude, whereas most of the retained catch was harvested from the Petrel Bank area ( $179^{\circ}$ W longitude to $179^{\circ}$ W longitude) during 1990/91-1994/95 (Figure 4). Retained catch and fishery CPUE (retained crab per pot lift) declined from 1993/94 to 1994/95 and 1995/96; retained catch in 1994/95 and, especially, 1995/96 was far below the lower GHL established. Due to concerns about the low stock level and poor recruitment indicated by results of the fishery in 1994/95-1995/96, the fishery was closed in 1996/97-1997/98. During 1998/99-2003/04 the
fishery was opened only in restricted areas, either as an open fishery managed under a GHL or as an ADF\&G-Industry survey conducted as a commissioner's permit fishery (Table 2); peak retained catch during that period was $229 \mathrm{t}(505,642 \mathrm{lb})$ harvested from the Petrel Bank area in 2002/03. The fishery has been closed during 2004/05-2016/17.

Only males of a minimum legal size may be retained by the commercial red king crab fishery in the WAI. By State of Alaska regulation ( $\mathbf{5}$ AAC 34.620 (a)), the minimum legal size limit is 6.5inches ( 165 mm ) carapace width ( CW ), including spines. A carapace length ( CL ) $\geq 138 \mathrm{~mm}$ is used to identify legal-size males when CW measurements are not available (Table 3-5 in NPFMC 2007). Except for the years 1968-1970, the minimum size has been 6.5 -inches CW since 1950; in 1968 there was a "first-season" minimum size of 6.5 -inches CW and a "secondseason" minimum size of 7.0 -inches and in 1969-1970 the minimum size was 7.0-inches CW (Donaldson and Donaldson 1992).

Red king crab may be commercially fished only with king crab pots (as defined in 5 AAC 34.050). Pots used to fish for red king crab in the WAI must, since 1996, have at least one-third of one vertical surface of the pot composed of not less than nine-inch stretched mesh webbing to permit escapement of undersized red king crab and may not be longlined ( $\mathbf{5}$ AAC 34.625 (e)). The sidewall of the pot "...must contain an opening equal to or exceeding 18 inches in length... The opening must be laced, sewn, or secured together by a single length of untreated, 100 percent cotton twine, no larger than 30 thread." (5 AAC 39.145(1)).

The WAI red king crab fishery west of $179^{\circ} \mathrm{W}$ longitude has been managed since 2005/06 under the Crab Rationalization program (50 CFR Parts 679 and 680). The WAI red king crab fishery in the area east of $179^{\circ} \mathrm{W}$ longitude was not included in the Crab Rationalization program (Baechler and Cook 2014). In March 2014 the Alaska Board of Fisheries established two red king crab management districts in state regulations for the Aleutian Islands west of $171^{\circ}$ W longitude (the Adak District, $171^{\circ}$ to $179^{\circ} \mathrm{W}$ longitude; and the Petrel District, west of $179^{\circ}$ W longitude) and some notable differences in regulations exist between the two districts. The red king crab commercial fishing season in the Adak District is August 1 to February 15, unless closed by emergency order ( $\mathbf{5}$ AAC 34.610 (a) (1)); the red king crab commercial fishing season in the Petrel is October 15 to February 15, unless closed by emergency order ( $\mathbf{5}$ AAC 34.610 (a) (2)). Only vessels 60 feet or less in overall length may participate in the commercial red king crab fishery within the state waters of the Adak District ( $\mathbf{5}$ AAC $\mathbf{3 4 . 6 1 0}$ (d)); no vessel size limit is established for federal waters in the Adak District or for state or federal waters in the Petrel District. Federal waters in the Adak District are opened to commercial red king crab fishing only if the season harvest level established by ADF\&G for the Adak District is $250,000 \mathrm{lb}$ or more ( $\mathbf{5}$ AAC 34.616 (a) (2)); there is no comparable regulation for the Petrel District. In the Adak District, pots commercially fished for red king crab may only be deployed and retrieved between 8:00 AM and 5:59 PM each day (5 AAC 34.625 (g) (2)) and the following pot limits pertain: 10 pots per vessel for vessels fishing within state waters ( $\mathbf{5}$ AAC $\mathbf{3 4 . 6 2 5}$ (g) (1) (A)); and 15 pots per vessel for vessels fishing in federal waters ( $\mathbf{5}$ AAC 34.625 (g) (1) (B)). In the Petrel District there is no regulation pertaining to periods for operation of gear and a pot limit of 250 pots per vessel (5 AAC 34.625 (d)). See also " 6 . Brief description of the annual ADF\&G harvest strategy," below.

## 6. Brief description of the annual ADF\&G harvest strategy:

Prior to the March 2014 Alaska Board of Fisheries meeting, when the board adopted a harvest strategy for the Adak District only, there was no harvest strategy in state regulation for WAI red king crab. Following results of the January/February and November 2001 ADF\&G-Industry pot surveys for red king crab in the Petrel Bank area, which produced high catch rates of legal males (CPUE $=28$ ), but low catches of females and sublegal males, ADF\&G opened the fishery in $2002 / 03$ and $2003 / 04$ with a GHL of $227 \mathrm{t}(500,000 \mathrm{lb})$; that GHL was established as the minimum GHL that could be managed inseason, given expected participation and effort (Baechler and Cook 2014). The fishery was closed in 2004/05 due to continued uncertainty on the status of pre-recruit legal males, a reduction in legal male CPUE from 18 in 2002/03 to 10 in 2003/04, and a strategy adopted by ADF\&G to close the fishery before the CPUE of legal crab dropped below 10 .

The harvest strategy for red king crab in the Adak District adopted by the Alaska Board of Fisheries in March 2014 is as follows:

5 AAC 34.616. Adak District red king crab harvest strategy. (a) In the Adak District, based on the best scientific information available, if the department determines that there is a harvestable surplus of
(1) red king crab available in the waters of Alaska in the Adak District, the commissioner may open, by emergency order, a commercial red king crab fishery only in the waters of Alaska in the Adak District under 5 AAC 34.610(a)(1);
(2) at least 250,000 pounds of red king crab in the Adak District, the commissioner may open, by emergency order, a commercial red king crab fishery in the entire Adak District under 5 AAC 34.610(a)(1).
(b) In the Adak District, during a season opened under 5 AAC 34.610(a)(1), the operator of a validly registered king crab fishing vessel shall
(1) report each day to the department
(A) the number of pot lifts;
(B) the number of crab retained for the 24 -hour fishing period preceding the report; and
(C) any other information the commissioner determines is necessary for the management and conservation of the fishery, as specified in the vessel registration certificate issued under 5 AAC 34.020; and
(2) complete and submit a logbook as prescribed and provided by the department.
7. Summary of the history of BMSY: Not applicable for this Tier 5 stock.

## D. Data

## 1. Summary of new information:

- Retained catch data from the 2016/17 directed fishery has been added; the fishery was closed and the retained catch was $0 \mathrm{t}(0 \mathrm{lb})$.
- Data on discarded catch in crab and groundfish fisheries has been updated with data from the 2016/17 Aleutian Islands golden king crab fishery and the 2016/17 groundfish fisheries in reporting areas 541, 542, and 543 (Figure 5).
- Discarded catch during the cooperative industry-ADF\&G survey in 2016. Data was available as number of crab caught per size/sex group (males: legal, sub-lagal, and females). Assumptions were made on the representative size (width) of each group, which were converted to length then weight. A bycatch mortality rate of 0.2 (as applied to crab fisheries) was applied to the estimated total weight caught.

## 2. Data presented as time series:

a. Total catch and b. Information on bycatch and discards:

- Annual retained catch weight for 1960/61-2016/17 (Tables 1a and 1b, Figure 3).
- Annual retained catch weight and estimated weights of discarded legal males, discarded sublegal males, and discarded females captured by commercial crab fisheries during 1995/96-2016/17 (Table 3). Observer data on size distributions and estimated catch numbers of discarded catch were used to estimate the weight of discarded catch of red king crab by applying a weight-at-length estimator (see below). Estimates of discarded catch prior to 1995/96 are not given due to non-existence of data or to limitations on sampling for discarded catch during the crab fisheries: prior to $1988 / 89$ there was no fishery observer program for Aleutian Islands crab fisheries and observers were required only on vessels processing king crab at sea (including catcher-processor vessels) during 1988/89-1994/95; observer data from the Aleutian Islands prior to 1990/91 is considered unreliable; and the observer data from the directed WAI red king crab fishery in 1990/91 and 1992/93-1994/95 and golden king crab fishery in the 1993/94-1994/95 are confidential due to the limited number of observed vessels. During 1995/96-2004/05, observers were required on all vessels fishing for king crab in the Aleutian Islands area at all times that a vessel was fishing. With the advent of the Crab Rationalization program in 2005/06, all vessels fishing for golden king crab in the Aleutian Islands area are now required to carry an observer for a period during which $50 \%$ of the vessel's retained catch was obtained during each trimester of the fishery; observers continue to be required at all times on a vessel fishing in the red king crab fishery west of $179^{\circ} \mathrm{W}$ longitude. All red king crab that were captured and discarded during the Aleutian Islands golden king crab fishery west of $174^{\circ} \mathrm{W}$ longitude by a vessel while an observer was on board during 2001/02-2002/03 and 2004/05-2016/17 were counted and recorded for capture location and biological data.
- Annual estimated weight of discarded catch and estimated bycatch mortality in the WAI (reporting areas 541, 542, and 543; i.e., Aleutian Islands west of $170^{\circ} \mathrm{W}$ longitude; Figure 5) during federal groundfish fisheries by gear type (fixed or trawl) for 1993/942016/17 (Table 4). Following Foy (2012a, 2012b), the bycatch mortality rate of king crab captured by fixed gear during groundfish fisheries was assumed to be 0.5 and of king crab captured by trawls during groundfish fisheries was assumed to be 0.8 . Estimates of discarded catch by gear type for 1992/93 are available, but appear to be suspect because
they are extremely low. Annual estimated weight of discarded catch during federal groundfish fisheries by reporting area (541, 542, and 543) for 1993/94-2016/17 is also presented in Table 5.
- Annual estimated weight of total fishery mortality for 1995/96-2016/17, partitioned into retained catch, estimated bycatch mortality during crab fisheries, and estimated bycatch mortality during federal groundfish fisheries (Table 6). Following Siddeek et al. (2011), the bycatch mortality rate of king crab captured and discarded during Aleutian Islands king crab fisheries was assumed to be 0.2 ; bycatch mortality in crab fisheries was estimated for Table 6 by applying that assumed bycatch mortality rate to the estimates of discarded catch given in Table 3. The estimates of bycatch mortality in groundfish fisheries given in Table 6 are from Table 4.
- Table 7 summarizes the available data on retained catch weight and estimates of discarded catch weight.
c. Catch-at-length: Although not used in a Tier 5 assessment, available retained-catch size frequency sample data from 1960/61-2016/17 are summarized and presented (Appendices A1-A4).
d. Survey biomass estimates: Not available; there is no program for regular performance of standardized surveys sampling from the entirety of the stock range.
e. Survey catch at length: Not used in a Tier 5 assessment; none are presented.
f. Other data time series: Although not used in a Tier 5 assessment, available data on CPUE (retained crab per pot lift) from 1972/73-2016/17 directed fisheries are presented (Table 1, Figure 6).

3. Data which may be aggregated over time:
a. Growth-per-molt; frequency of molting, etc. (by sex and perhaps maturity state):

Not used in a Tier 5 assessment. Growth per molt was estimated for WAI male red king crab by Vining et al. (2002) based on information received from recoveries during commercial fisheries of tagged red king crab released in the Adak Island to Amlia Island area during the 1970s (see Table 5 in Pengilly 2009). Vining et al. (2002) used a logit estimator to estimate the probability as a function of carapace length (CL, mm) at release that a male WAI red king tagged and released in new-shell condition would molt within 8-14 months after release (see Tables 6 and 7 in Pengilly 2009).

## b. Weight-at length or weight-at-age (by sex):

Parameters (A and B) used for estimating weight (g) from carapace length (CL, mm) of male and female red king crab according to the equation, Weight $=\mathrm{A}^{*} \mathrm{CL}^{\mathrm{B}}$ (from Table 3-5, NPFMC 2007) are: $\mathrm{A}=0.000361$ and $\mathrm{B}=3.16$ for males and $\mathrm{A}=0.022863$ and $\mathrm{B}=2.23382$ for females; note that although the estimated parameters, A and B , are those estimated for ovigerous females, those parameters were used to estimate the weight of all females without regard to reproductive status. Estimated weights in grams were converted to lb by dividing by 453.6.

## c. Natural mortality rate:

Not used in a Tier 5 assessment. NPFMC (2007) assumed a natural mortality rate of $\mathrm{M}=0.18$ for king crab species, but natural mortality rate has not been estimated specifically for red king crab in the WAI.
4. Information on any data sources that were available, but were excluded from the assessment:

- Distribution of effort and catch during the 2006 ADF\&G Petrel Bank red king crab pot survey (Gish 2007) and the 2009 ADF\&G Petrel Bank red king crab pot survey (Gish 2010).
- Sex-size distribution of catch and distribution of effort and catch during the January/February 2001 and November 2001 ADF\&G-Industry red king crab survey of the Petrel Bank area (Bowers et al. 2002) and ADF\&G-Industry red king crab pot survey conducted as a commissioner's permit fishery in November 2002 in the Adak Island and Atka-Amlia Islands areas (Granath 2003).
- Observer data on size distribution and geographic distribution of discarded catch of red king crab in the WAI red king crab fishery and the Aleutian Islands golden king crab fishery, 1988/89-2016/17 (ADF\&G observer database).
- Summary of data collected by ADF\&G WAI red king crab fishery observers or surveys during 1969-1987 (Blau 1993).

## E. Analytic Approach

1. History of modeling approaches for this stock: This is a Tier 5 assessment.
2. Model Description: Subsections a-i are not applicable to a Tier 5 assessment.

There is no regular survey of this stock. No assessment model for the WAI red king crab stock exists and none is in development. The SSC in June 2010 recommended that: the WAI red king crab stock be managed as a Tier 5 stock; the OFL be specified as a total-catch OFL; the totalcatch OFL be established as the estimated average annual weight of the retained catch and bycatch mortality in crab and groundfish fisheries over the period 1995/96-2007/08; and the period used for computing the Tier 5 total-catch OFL be fixed at 1995/96-2007/08.

Given the strong recommendations from the SSC in June 2010, Tier 5 total-catch OFLs would change only if retained catch data and estimates of discarded catch for the period 1995/962007/08 or assumed values of bycatch mortality rates used in the 2010 SAFE were revised. Given that no need has been shown to revise either the retained catch data or the discarded catch estimates for the period 1995/96-2007/08 or assumed values of bycatch mortality rates used in the 2010 SAFE, the recommended approach for establishing the 2017/18 OFL is the approach identified by the SSC in June 2010 and no alternative approaches are suggested by the author. Hence the recommended total-catch OFL for 2017/18 is computed according to the status quo "Alternative 1" approach as:

$$
\mathrm{OFL}_{2017 / 18}=\mathrm{RET}_{95 / 96-07 / 08}+\mathrm{BM}_{\mathrm{CF}, 95 / 96-07 / 08}+\mathrm{BM}_{\mathrm{GF}, 95 / 96-07 / 08},
$$

where,

- $\mathrm{RET}_{95 / 96-07 / 08}$ is the average annual retained catch in the directed crab fishery during 1995/96-2007/08
- $\mathrm{BM}_{\mathrm{CF}, 95 / 96-07 / 08}$ is the estimated average annual bycatch mortality in the directed and non-directed crab fisheries during 1995/96-2007/08, and
- $\mathrm{BM}_{\mathrm{GF}, 95 / 96-07 / 08}$ is the estimated average annual bycatch mortality in the groundfish fisheries during 1995/96-2007/08.

Given the June 2010 SSC recommendations, items $\boldsymbol{E} .2 \boldsymbol{a}-\boldsymbol{i}$ are not applicable.

## 3. Model Selection and Evaluation:

a. Description of alternative model configurations

Not applicable; see section E.2.
b. Show a progression of results from the previous assessment to the preferred base model by adding each new data source and each model modification in turn to enable the impacts of these changes to be assessed: None; see section A.4.
c. Evidence of search for balance between realistic (but possibly over-parameterized) and simpler (but not realistic) models: None; see the section A.4.
d. Convergence status and convergence criteria for the base-case model (or proposed basecase model): Not applicable.
e. Table (or plot) of the sample sizes assumed for the compositional data: Not applicable.
f. Do parameter estimates for all models make sense, are they credible?:

Use of the 1995/96-2007/08 time period for estimating annual total fishery mortality and computing a Tier 5 OFL was established by the SSC in 2010.
g. Description of criteria used to evaluate the model or to choose among alternative models, including the role (if any) of uncertainty: Use of the 1995/96-2007/08 time period for estimating annual total fishery mortality and computing a Tier 5 OFL was established by the SSC in 2010.
h. Residual analysis (e.g. residual plots, time series plots of observed and predicted values or other approach): Not applicable.
i. Evaluation of the model, if only one model is presented; or evaluation of alternative models and selection of final model, if more than one model is presented: The model follows the June 2010 SSC recommendations to freeze the time period for estimation of the Tier 5 OFL.

## 4. Results (best model(s)):

a. List of effective sample sizes, the weighting factors applied when fitting the indices, and the weighting factors applied to any penalties: Not applicable to a Tier 5 assessment.
b. Tables of estimates (all quantities should be accompanied by confidence intervals or other statistical measures of uncertainty, unless infeasible; include estimates from previous SAFEs for retrospective comparisons): See Table 6.
c. Graphs of estimates (all quantities should be accompanied by confidence intervals or other statistical measures of uncertainty, unless infeasible): $\quad$ Not applicable to a Tier 5 assessment.
d. Evaluation of the fit to the data: Not applicable to a Tier 5 assessment.
e. Retrospective and historic analyses (retrospective analyses involve taking the "best" model and truncating the time-series of data on which the assessment is based; a historic analysis involves plotting the results from previous assessments): $N$ Not applicable to a Tier 5 assessment.
f. Uncertainty and sensitivity analyses (this section should highlight unresolved problems and major uncertainties, along with any special issues that complicate scientific assessment, including questions about the best model, etc.): For a Tier 5 assessment, the major uncertainties are:

- Whether the time period is "representative of the production potential of the stock" and if it serves to "provide the required risk aversion for stock conservation and utilization goals." Or whether any such time period exists.
- In this regard, the CPT (May 2011 minutes) noted that the OFL ( 56 t ; 0.12-million lb) that was established for this stock by the SSC in June 2010 "could be considered biased high because of years of high exploitation" and questioned "whether the time frame used to compute the OFL is meaningful as an estimate of the productivity potential of this stock."
- The bycatch mortality rates used in estimation of total catch. Being as most $(78 \%)$ of the estimated total mortality during 1995/96-2007/08 is due to the retained catch component, the total catch estimate is not severely sensitive to the assumed bycatch mortality rates. Doubling the assumed bycatch mortality during crab fisheries from 0.2 to 0.4 would increase the OFL by a factor of 1.02 ; halving that assumed rate from 0.2 to 0.1 would decrease the OFL by a factor of 0.99 . Increasing the assumed bycatch mortality rate for all groundfish fisheries (regardless of gear type) to 1.0 , would increase the OFL by a factor of 1.07.

## F. Calculation of the OFL

1. Specification of the Tier level and stock status level for computing the OFL:

- Recommended as Tier 5, total-catch OFL computed as the estimated average annual total catch over a specified period.
- Recommended time period for computing retained-catch portion of the OFL: 1995/962007/08.
- Recommended time period for computing bycatch mortality due to crab fisheries: 1995/96-2007/08.
- Recommended time period for computing bycatch mortality due to groundfish fisheries: 1995/96-2007/08.
- Recommended bycatch mortality rates: 0.2 for crab fisheries; 0.5 for fixed-gear groundfish fisheries; 0.8 for trawl groundfish fisheries.
- Recommended OFL for 2017/18 is estimated by,

$$
\mathrm{OFL}_{2017 / 18}=\mathrm{RET}_{95 / 96-07 / 08}+\mathrm{BM}_{\mathrm{CF}, 95 / 96-07 / 08}+\mathrm{BM}_{\mathrm{GF}, 95 / 96-07 / 08},
$$

where,

- $\mathrm{RET}_{95 / 96-07 / 08}$ is the average annual retained catch in the directed crab fishery during 1995/96-2007/08
- $\mathrm{BM}_{\mathrm{CF}, 95 / 96-07 / 08}$ is the estimated average annual bycatch mortality in the directed and non-directed crab fisheries during 1995/96-2007/08, and
- $\mathrm{BM}_{\mathrm{GF}, 95 / 96-07 / 08}$ is the estimated average annual bycatch mortality in the groundfish fisheries during 1995/96-2007/08.

Statistics on the data and estimates used to calculate $\mathrm{RET}_{95 / 96-07 / 08}, \mathrm{BM}_{\mathrm{CF}}, 95 / 96-07 / 08$, and $\mathrm{BM}_{\mathrm{GF}, 95 / 96-07 / 08}$ are provided in the "Mean, 1995/96-2007/08" row of Table 6. Using the calculated values of $\mathrm{RET}_{95 / 96-07 / 08}, \mathrm{BM}_{\mathrm{CF}, 95 / 96-07 / 08}$, and $\mathrm{BM}_{\mathrm{GF}, 95 / 96-07 / 08}, \mathrm{OFL}_{2016 / 17}$ is,

$$
\mathrm{OFL}_{2017 / 18}=43.97 \mathrm{t}+1.36 \mathrm{t}+10.86 \mathrm{t}=56 \mathrm{t}(123,867 \mathrm{lb})
$$

2. List of parameter and stock size estimates (or best available proxies thereof) required by limit and target control rules specified in the fishery management plan: Not applicable to Tier 5 assessment.

## 3. Specification of the OFL:

a. Provide the equations (from Amendment 24) on which the OFL is to be based:

From Federal Register / Vol. 73, No. 116, page 33926, "For stocks in Tier 5, the overfishing level is specified in terms of an average catch value over an historical time period, unless the Scientific and Statistical Committee recommends an alternative value based on the best available scientific information." Additionally, "For stocks where nontarget fishery removal data are available, catch includes all fishery removals, including retained catch and discard losses. Discard losses will be determined by multiplying the appropriate handling mortality rate by observer estimates of bycatch discards. For stocks where only retained catch information is available, the overfishing level is set for and compared to the retained catch" (FR/Vol. 73, No. 116, 33926). That compares with the specification of NPFMC (2007) that the OFL "represent[s]
the average retained catch from a time period determined to be representative of the production potential of the stock."
b. Basis for projecting MMB to the time of mating: Not applicable to Tier 5 assessment.
c. Specification of Fofl $^{\text {, OFL, and other applicable measures (if any) relevant to determining }}$ whether the stock is overfished or if overfishing is occurring: See Management Performance tables, below. No vessels participated in the 2016/17 directed fishery and but some bycatch was observed in the Aleutian Islands golden king crab fishery in 2016/17. Total catch mortality in 2016/17 consists of what occurred during the Aleutian Islands golden king crab fishery and groundfish fisheries ( 0.18 t ) and the cooperative industry-ADF\&G survey ( 0.03 t ). Overfishing did not occur in 2016/17. The OFL and ABC values for 2017/18 in the table below are the author's recommended values. The 2017/18 TAC has not yet been established.

Management Performance Table (values in t)

| Fishing <br> Year | MSST | Biomass <br> (MMB) | TAC $^{\text {a }}$ | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2012 / 13$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2013 / 14$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2014 / 15$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2015 / 16$ | N/A | N/A | Closed | 0 | 1.3 | 56 | 34 |
| $2016 / 17$ | N/A | N/A | Closed | 0 | $<1$ | 56 | 34 |
| $2017 / 18$ | N/A | N/A |  |  |  | 56 | 14 |

a. Pre-season harvest levels are established as total allowable catch for the rationalized fishery west of $179^{\circ} \mathrm{W}$ longitude and as a guideline harvest level for the non-rationalized fishery east of $179^{\circ} \mathrm{W}$ longitude.

Management Performance Table (values in lb)

| Fishing <br> Year | MSST | Biomass <br> (MMB) | TAC $^{\mathbf{a}}$ | Retained <br> Catch | Total <br> Catch | OFL | ABC |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2012 / 13$ | N/A | N/A | Closed | 0 | 624 | 123,867 | 74,320 |
| $2013 / 14$ | N/A | N/A | Closed | 0 | 732 | 123,867 | 74,320 |
| $2014 / 15$ | N/A | N/A | Closed | 0 | 474 | 123,867 | 74,320 |
| $2015 / 16$ | N/A | N/A | Closed | 0 | 2,964 | 123,867 | 74,320 |
| $2016 / 17$ | N/A | N/A | Closed | 0 | 454 | 123,867 | 74,320 |
| $2017 / 18$ | N/A | N/A |  |  |  | 123,867 | 30,967 |

a. Pre-season harvest levels are established as total allowable catch for the rationalized fishery west of $179^{\circ} \mathrm{W}$ longitude and as a guideline harvest level for the non-rationalized fishery east of $179^{\circ} \mathrm{W}$ longitude.
4. Specification of the recommended retained-catch portion of the total-catch OFL:
a. Equation for recommended retained portion of the total-catch OFL,

Retained-catch portion $=$ average retained catch during 1995/96-2007/08

$$
=44 \text { t (96,932 lb). }
$$

5. Recommended Fofl, OFL total catch and the retained portion for the coming year:

See sections $\boldsymbol{F} .3$ and $\boldsymbol{F} .4$, above; no FofL is recommended for a Tier 5 assessment.

## G. Calculation of ABC

1. PDF of OFL. A bootstrap estimate of the sampling distribution (assuming no error in estimation of the discarded catch) of the OFL is shown in Figure 7 (the sample means of 1,000 samples drawn with replacement from the 1995/96-2007/08 estimates of total fishery mortality in Table 6). The mean ( 56 t ) and CV ( 0.42 ) computed from the 1,000 replicates are essentially the same as for the mean and CV of the 1995/96-2007/08 total catch estimates given in Table 6. Note that generated sampling distribution is meaningful as a measure in the uncertainty of the OFL only if assumptions on the choice of years used to compute the Tier 5 OFL are true (see Section E.4.f).

## 2. List of variables related to scientific uncertainty.

- The time period to compute the average catch relative to the assumption that it represents "a time period determined to be representative of the production potential of the stock."
- Bycatch mortality rate in each fishery that bycatch occurs. Note that for a Tier 5 assessment, an increase in an assumed bycatch mortality rate will increase the OFL (and hence the ABC ), but has no effect on the retained catch portion of the OFL or the retained catch portion of the $A B C$.
- Estimated discarded catch and bycatch mortality during each fishery that bycatch occurred in during 1995/96-2007/08.

3. List of additional uncertainties for alternative sigma-b. Not applicable to this Tier 5 assessment.
4. Author recommended ABC: $14 \mathrm{t}(30,967 \mathrm{lb})$. This is lower than the ABC that has been recommended by the author since the SSC recommended a $34 \mathrm{t}(74,320 \mathrm{lb}) \mathrm{ABC}$ for $2012 / 13$. The SSC's recommended ABC of 34 t for 2012/13 was determined as a value "sufficient to cover bycatch and the proposed test fishery catch" (June 2012 SSC meeting minutes, page 10). It provides a $40 \%$ buffer on the OFL of $56 \mathrm{t}(123,867 \mathrm{lb})$. However, the industry has not expressed interest in conducting a test fishery for 2017/18. Further, the 2016 Petrel survey indicated the stock is severely depressed. Thus, the author and CPT recommend increasing the buffer to $75 \%$.

## H. Rebuilding Analyses

Entire section is not applicable; this stock has not been declared overfished.

## I. Data Gaps and Research Priorities

This fishery has a long history, with the domestic fishery dating back to 1960/61. However, much of the data on this stock prior to the early-mid 1980s is difficult to retrieve for analysis. Fishery data summarized to the level of statistical area are presently not available prior to 1980/81. Changes in definitions of fishery statistical areas between 1984/85 and 1985/86 also make it difficult to assess geographic trends in effort and catch over much of the fishery's history. An effort to compile all fishery data and other written documentation on the stock and fishery and to enter all existing fishery, observer, survey, and tagging data into a database that
allows for analysis of all data from the fishery and stock through the history of the fishery would be time-consuming, challenging, and - perhaps - disappointing, but could provide valuable information if successful.

The SSC in October 2008, June 2011, and June 2013 noted the need for systematic surveys to obtain the data to estimate the biomass of this stock. Surveys on this stock have, however, been few and the geographic scope of the surveyed area is limited. Aside from the pot surveys performed in the Adak-Atka area during the mid-1970s (ADF\&G 1978, Blau 1993), the only standardized surveys for red king crab performed by ADF\&G were performed in November 2006 and November 2009 and those were limited to the Petrel Bank area (Gish 2007, 2010). ADF\&G-Industry surveys, conducted as limited fisheries that allowed retention of captured legal males under provisions of a commissioner's permit, have been performed in limited areas of the WAI: during January-February 2001 and November 2001 in the Petrel Bank area (Bowers et al. 2002) and during November 2002 in the Adak-Atka-Amlia area (Granath 2003). A very limited (18 pot lifts) Industry exploratory survey without any retention of crab was performed during mid-October to mid-December 2009 between $178^{\circ} 00^{\prime}$ E longitude and $175^{\circ} 30^{\prime}$ E longitude produced a catch of one red king crab, a legal-sized male (Baechler and Cook 2014). Based on requests from Industry in 2012, ADF\&G designed a state-waters red king crab pot survey for the Adak Island group. Twenty-five stations were designated with 20 pot lifts in each station. To defray cost of the survey, participants would be allowed to sell up to $14 \mathrm{t}(31,417 \mathrm{lb})$ of red king crab. In addition, bycatch mortality during the proposed survey was assumed not to exceed 9 t based on assumed maximum discarded catch weight and an assumed bycatch mortality rate of 0.2. In 2012 the CPT and SSC recommended an ABC of 34 t (0.74-million lb) for 2012/13 to accommodate total fishery mortality due the proposed red king crab survey in addition to estimated bycatch mortality due to non-directed fisheries (12 t). In late summer 2012, Industry advocates decided to forgo the fall 2012 survey.

Trawl surveys are preferable relative to pot surveys for providing density estimates, but crab pots may be the only practical gear for sampling king crab in the Aleutians. Standardized pot surveys are a prohibitively expensive approach to surveying the entire WAI. Surveys or exploratory fishing performed by industry in cooperation with ADF\&G, with or without allowing retention of captured legal males, reduce the costs to agencies. Agency-Industry cooperation can provide a means to obtain some information on distribution and density during periods of fishery closures. However, there can be difficulties in assuring standardization of procedures during ADF\&GIndustry surveys (Bowers et al. 2002). Moreover, costs of performing a survey have resulted in incompletion of ADF\&G-Industry surveys (Granath 2003). Hence surveys performed by Industry in cooperation with ADF\&G cannot be expected to provide sampling over the entire WAI during periods of limited stock distribution and overall low density, as apparently currently exists.

A cooperative survey between industry and ADF\&G was performed in the Adak area in September 2015 (Hilsinger et al. 2016a). A total of 442 red king crab ( 23 legal males, 74 pre recruit males, 140 juvenile males, and 204 females) were captured in Sitkin Sound and Expedition Harbor from 730 pots. Since RKC were highly aggregated (most were in inner Sitkin Sound) and few crab were legal males, further surveys of RKC in this area are a low priority. A cooperative survey between industry and ADF\&G was also performed in the Petrel area in

November 2016 (Hilsinger et al. 2016b). A total of 40 red king crab (39 legal males, 1 sub-legal male, and 0 females) were captured.

## List of Tables

Table 1a: page 24. Commercial fishery history for the western Aleutian Islands red king crab commercial fishery, 1960/61-2016/17: number of vessels, guideline harvest level (GHL; established in lb, converted to t) for 1973/74-2004/05, total allowable catch (TAC; established in lb , converted to $\mathbf{t}$ ) in the area west of $179^{\circ} \mathrm{W}$ longitude combined with GHL (established in lb , converted to $\mathbf{t}$ ) in the area east of $179^{\circ} \mathrm{W}$ longitude for 2005/06-2016/17, weight of retained catch (Harvest; $\mathbf{t}$ ), number of retained crab, pot lifts, fishery catch per unit effort (CPUE; retained crab per pot lift), and average weight ( $\mathbf{k g}$ ) of retained crab.

Table 1b: page 25. Commercial fishery history for the western Aleutian Islands red king crab commercial fishery, 1960/61-2016/17 number of vessels, guideline harvest level (GHL; lb) for 1973/74-2004/05, total allowable catch (TAC; lb) in the area west of $179^{\circ} \mathrm{W}$ longitude combined with GHL (lb) in the area east of $179^{\circ}$ W longitude for 2005/06-2016/17, weight of retained catch (Harvest; lb), number of retained crab, pot lifts, fishery catch per unit effort (CPUE; retained crab per pot lift), and average weight (lb) of retained crab.

Table 2: page 26. A summary of relevant fishery activities and management measures pertaining to the Western Aleutian Islands red king crab fishery since 1996/97.

Table 3: page 27. Annual retained catch (t) of Western Aleutian Islands red king crab, with the estimated annual discarded catch ( $\mathbf{t}$; not discounted for an assumed bycatch mortality rate) and components of discarded catch (legal males, sublegal males, and females) during commercial crab fisheries, 1995/96-2016/17.

Table 4: page 28. Estimated annual weight (t) of discarded catch of red king crab (all sizes, males and females) and estimated annual bycatch mortality ( $\mathbf{t}$ ) during federal groundfish fisheries by gear type (fixed or trawl) in reporting areas 541, 542, and 543 (Aleutian Islands west of $170^{\circ} \mathrm{W}$ longitude), 1993/94-2016/17 (assumes bycatch mortality rate of 0.5 for fixed-gear fisheries and 0.8 for trawl fisheries).

Table 5: page 29. Estimated annual weight of discarded catch ( $\mathbf{t}$; not discounted by an assumed bycatch mortality rate) of red king crab in reporting areas 541, 542, and 543 (Aleutian Islands west of $170^{\circ} \mathrm{W}$ longitude) during federal groundfish fisheries (all gear types combined) by reporting area, 1993/94-2016/17.

Table 6: page 30. Estimated annual weight (t) of total fishery mortality to Western Aleutian Islands red king crab, 1995/96-2016/17, partitioned by source of mortality: retained catch, estimated bycatch mortality during crab fisheries, and estimated bycatch mortality during groundfish fisheries.

Table 7: page 31. Annual retained catch weight (t) and estimates of annual discarded catch weight ( $\mathbf{t}$; not discounted for an assumed bycatch mortality rate) of Western Aleutian Islands red king crab available for a Tier 5 assessment; shaded, bold values are used in computation of the recommended (status quo) 2017/18 Tier 5 OFL.

## List of Figures

Figure 1: page 32. Aleutian Islands, Area O, red and golden king crab management area (from Baechler and Cook 2014, updated to show boundaries of the Adak and Petrel Districts for red king crab as established by the Alaska Board of Fisheries in March 2014).

Figure 2: page 33. Retained catch (t) in the Western Aleutian Islands red king crab fishery, 1985/86-1995/96 by 1-degree longitude grouping, summarized from fish ticket catch by state statistical area landing data.

Figure 3: page 34. Retained catch (t) in the Western Aleutian Islands red king crab fishery, 1960/61-2016/17 (catch is for the area west of $172^{\circ} \mathrm{W}$ longitude during 1960/61-1983/84 and for the area west of $171^{\circ} \mathrm{W}$ longitude during 1984/85-2016/17; see Table 1a).

Figure 4: page 34. Annual retained catch (t) in the Western Aleutian Islands red king crab fishery during 1985/86-1995/96, partitioned into three longitudinal zones: $171^{\circ} \mathrm{W}$ longitude to $179^{\circ} \mathrm{W}$ longitude (white bars); $179^{\circ} \mathrm{W}$ longitude to $179^{\circ} \mathrm{E}$ longitude (black bars); and $179^{\circ} \mathrm{E}$ longitude to $171^{\circ} \mathrm{E}$ longitude.

Figure 5: page 35. Map of federal groundfish fishery reporting areas for the Bering Sea and Aleutian Islands. Areas 541, 542, and 543 are used to obtain data on discarded catch of Western Aleutian Islands red king crab during groundfish fisheries (from http://www.alaskafisheries.noaa.gov/rr/figures/fig1.pdf).

Figure 6: page 36. Retained catch (number of crab) and CPUE (number of retained crab per pot lift) in the western Aleutian Islands red king crab fishery, 1972/73-2016/17 (from Table 1a). Data for 1972/73-1983/84 are for the area west of $172^{\circ}$ W longitude; data for 1984/85-1997/98, 1999/00, and 2004/05-2016/17 are for the area west of $171^{\circ} \mathrm{W}$ longitude; data for 1998/99 are for the area west of $174^{\circ} \mathrm{W}$ longitude; and data for 2000/01-2003/04 are for the area between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude.

Figure 7: page 37. Bootstrapped estimate of the sampling distribution of the recommended 2017/2018 Tier 5 OFL (total-catch, t) for the Western Aleutian Islands red king crab stock; histogram in left column, cumulative distribution in right column.

## List of Appendices

Appendix A1: page 38. Summary of retained catch size frequency data available from Western Aleutian Islands directed red king crab fishery, 1960/61-2016/17.

Appendix A2: page 39 Available retained catch size frequency sample data 1961/62-1979/80 western Aleutian Islands directed red king crab fishery.

Appendix A3: page 42. Available retained catch size frequency sample data 1980/81-1989/90 Western Aleutian Islands directed red king crab fishery.

Appendix A4: page 45. Available retained catch size frequency sample data 1990/91-2003/04 Western Aleutian Islands directed red king crab fishery.

Appendix A5. Page 49. Plot of available retained catch size frequency sample data 1961/622003/04 western Aleutian Islands directed red king crab fishery (data listed in Appendices A2-A4).

Table 1a. Commercial fishery history for the western Aleutian Islands red king crab commercial fishery, 1960/61-2016/17: number of vessels, guideline harvest level (GHL; established in lb, converted to t) for 1973/74-2004/05, total allowable catch (TAC; established in lb , converted to t ) in the area west of $179^{\circ} \mathrm{W}$ longitude combined with GHL (established in lb , converted to $\mathbf{t}$ ) in the area east of $179^{\circ} \mathrm{W}$ longitude for 2005/06-2016/17, weight of retained catch (Harvest; $\mathbf{t}$ ), number of retained crab, pot lifts, fishery catch per unit effort (CPUE; retained crab per pot lift), and average weight ( $\mathbf{k g}$ ) of retained crab.

[^10]Table 2. A summary of relevant fishery activities and management measures pertaining to the Western Aleutian Islands red king crab fishery since 1996/97.

| Crab <br> fishing year | Fishery Activities and Management Measures |
| :---: | :---: |
| $\begin{aligned} & \hline \text { 1996/97- } \\ & 1997 / 98 \\ & \hline \end{aligned}$ | - Fishery closed. |
| 1998/99 | - GHL of $7 \mathrm{t}(15,000 \mathrm{lb})$ for exploratory fishing with fishery closed in the Petrel Bank area (i.e., between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude) - 1 vessel |
| 1999/00 | - Fishery closed |
| 2000/01 | - Fishery closed <br> - Catch retained during ADF\&G-Industry survey of Petrel Bank area (i.e., between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude) conducted as commissioner's permit fishery, Jan-Feb 2001 1 vessel Retained catch weight $=35 \mathrm{t}(76,562 \mathrm{lb})$ CPUE $=23$ retained crab per pot lift |
| 2001/02 | - Fishery closed <br> - Catch retained ADF\&G-Industry survey of Petrel Bank area (i.e., between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude) conducted as commissioner's permit fishery, November 2001 4 vessels Retained catch weight $=70 \mathrm{t}(153,961 \mathrm{lb})$ CPUE $=39$ retained crab per pot lift |
| 2002/03 | - Fishery opened with GHL of $227 \mathrm{t}(500,000 \mathrm{lb})$ restricted to Petrel Bank area (i.e., between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude) 33 vessels <br> - Retained catch weight $=229 \mathrm{t}(505,642 \mathrm{lb})$ <br> - CPUE $=18$ retained crab per pot lift <br> - ADF\&G-Industry survey of the Adak, Atka, and Amlia Islands area conducted as a commissioner's permit fishery <br> - 4 legal males captured in 1,085 pot lifts |
| 2003/04 | - Fishery opened with GHL of $227 \mathrm{t}(500,000 \mathrm{lb})$ restricted to Petrel Bank area (i.e., between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude) 30 vessels Retained catch weight $=217 \mathrm{t}(479,113) \mathrm{lb}$ 10 retained crab per pot lift |
| $\begin{aligned} & \hline \text { 2004/05- } \\ & 2016 / 17 \end{aligned}$ | - Fishery closed <br> - 2006 and 2009 ADF\&G pot surveys on Petrel Bank <br> - 2015 exploratory/reconnaissance survey in Adak Island area. <br> - 2016 exploratory/reconnaissance survey in the Petrel Bank area. |

Table 3. Annual retained catch (t) of Western Aleutian Islands red king crab, with the estimated annual discarded catch ( $\mathbf{t}$; not discounted for an assumed bycatch mortality rate) and components of discarded catch (legal males, sublegal males, and females) during commercial crab fisheries, 1995/96-2016/17.

| Crab fishing year | WAI red king crab fishery |  |  |  | AI golden king crab fishery |  |  | Total Discarded |

a. No discarded catch data was available from the 1998/99 directed fishery for red king crab (see Table 2); bycatch mortality due to the 1998/99 crab fisheries was estimated by multiplying the retained catch for the 1998/99 directed red king crab fishery by the ratio of the 1995/96 bycatch mortality in crab fisheries to the 1995/96 retained catch.

Table 7. Annual retained catch weight ( $\mathbf{t}$ ) and estimates of annual discarded catch weight ( $\mathbf{t}$; not discounted for an assumed bycatch mortality rate) of Western Aleutian Islands red king crab available for a Tier 5 assessment; shaded, bold values are used in computation of the recommended (status quo) 2017/18 Tier 5 OFL.

| Crab Fishing Year | Retained catch weight | Discarded catch weight (estimated) |  |  |
| :---: | :---: | :---: | :---: | :---: |

Figure 1. Aleutian Islands, Area O, red and golden king crab management area (from Baechler and Cook 2014, updated to show boundaries of the Adak and Petrel Districts for red king crab as established by the Alaska Board of Fisheries in March 2014).

Figure 2. Retained catch (t) in the Western Aleutian Islands red king crab fishery, 1985/861995/96 by 1-degree longitude grouping, summarized from fish ticket catch by state statistical area landing data.

Figure 3. Retained catch ( $\mathbf{t}$ ) in the Western Aleutian Islands red king crab fishery, 1960/612016/17 (catch is for the area west of $172^{\circ} \mathrm{W}$ longitude during 1960/61-1983/84 and for the area west of $171^{\circ} \mathrm{W}$ longitude during 1984/85-2016/17; see Table 1a).

-171E-179E ■179E-179 W ם171 W-179 W
Figure 4. Annual retained catch ( $\mathbf{t}$ ) in the Western Aleutian Islands red king crab fishery during 1985/86-1995/96, partitioned into three longitudinal zones: $171^{\circ} \mathrm{W}$ longitude to $179^{\circ}$ W longitude (white bars); $179^{\circ} \mathrm{W}$ longitude to $179^{\circ} \mathrm{E}$ longitude (black bars); and $179^{\circ}$ E longitude to $171^{\circ} \mathrm{E}$ longitude.

Figure 5. Map of federal groundfish fishery reporting areas for the Bering Sea and Aleutian Islands. Areas 541, 542, and 543 are used to obtain data on discarded catch of Western Aleutian Islands red king crab during groundfish fisheries (from http://www.alaskafisheries.noaa.gov/rr/figures/fig1.pdf).

Figure 6. Retained catch (number of crab) and CPUE (number of retained crab per pot lift) in the western Aleutian Islands red king crab fishery, 1972/73-2016/17 (from Table 1a). Data for 1972/73-1983/84 are for the area west of $172^{\circ}$ W longitude; data for 1984/851997/98, 1999/00, and 2004/05-2016/17 are for the area west of $171^{\circ} \mathrm{W}$ longitude; data for 1998/99 are for the area west of $174^{\circ} \mathrm{W}$ longitude; and data for 2000/01$2003 / 04$ are for the area between $179^{\circ} \mathrm{W}$ longitude and $179^{\circ} \mathrm{E}$ longitude.

Figure 7. Bootstrapped estimate of the sampling distribution of the recommended 2016/2017 Tier 5 OFL (total-catch, t) for the Western Aleutian Islands red king crab stock; histogram in left column, cumulative distribution in right column.

Appendix A1. Summary of retained catch size frequency data available from Western Aleutian Islands directed red king crab fishery, 1960/61-2015/16.

Appendix A5. Page 1 of 1. Plot of available retained catch size frequency sample data 1961/622003/04 western Aleutian Islands directed red king crab fishery (data listed in Appendices A2-A4).

Western Aleutian Islands Red King Crab

Carapace length (mm)

[^0]:    ${ }^{[1]}$ As estimated in the 2018 assessment.
    ${ }^{[2]}$ For stocks 1-6 MMB on 2/15/2017 is estimated using the current assessment in September 2018. For Norton Sound red king crab MMB on 2/1/2017 is estimated using the current assessment in January 2017.

[^1]:    A-Calculated from the assessment reviewed by the Crab Plan Team in 20XX of 20XX/(XX+1) or based on the author's preferred model for 2018/19.
    B-Nominal rate of natural mortality. Actual rates used in the assessment are estimated and may be different.
